PART 3
CHAPTER 1 General
SECTION 1 Definitions

1 Application
The following definitions of terms apply throughout the requirements in these Rules.

3 Length

3.1 Scantling Length ($L$) (2018)
$L$ is the distance in meters (feet) on the summer load line from the fore side of the stem to the centerline of the rudder stock. For use with the Rules, $L$ is not to be less than 96% and need not be greater than 97% of the extreme length on the summer load line. The forward end of $L$ is to coincide with the fore side of the stem on the waterline on which $L$ is measured.

3.3 Freeboard Length ($L_f$) (2018)
$L_f$ is the distance in meters (feet) on a waterline at 85% of the least molded depth measured from the top of the keel from the fore side of the stem to the centerline of the rudder stock or 96% of the length on that waterline, whichever is greater. Where the stem is a fair concave curve above the waterline at 85% of the least molded depth and where the aftmost point of the stem is above the waterline, the forward end of the length, $L_f$, is to be taken at the aftmost point of the stem above that waterline. See 3-1-1/3.3 FIGURE 1.

In craft designed with a raked keel, the waterline on which this length is measured is to be parallel to the designed waterline.

FIGURE 1

5 Breadth
$B$ is the greatest molded breadth, in meters (feet).
Breadth used in 3-2-1/1.1.1 for craft which have flare or tumblehome, is the mean breadth of the waterline breadth and the maximum breadth between the waterline and main deck at the longitudinal center of flotation (LCF).

7 Depth

$D$ is the molded depth, in meters (feet), measured at the middle of the length $L$, from the molded keel line to the top of the freeboard deck beams at the side of the craft. On craft with rabbeted keel construction, $D$ is to be measured from the rabbet line. In cases where watertight bulkheads extend to a deck above the freeboard deck and are to be recorded in the Record as effective to that deck, $D$ is to be measured to the bulkhead deck.

9 Draft for Scantlings

$d$ is the draft, in meters (feet), measured at the middle of the length $L$ from the molded keel or the rabbet line at its lowest point to the estimated summer load waterline or the design load waterline in the displacement mode.

11 Decks

11.1 Freeboard Deck (2018)

The freeboard deck is normally the uppermost complete deck exposed to weather and sea, which has permanent means of closing all openings in its weather portions, and below which all openings in the craft side are equipped with permanent means for watertight closure.

In cases where a craft is designed for a special draft considerably less than that corresponding to the least freeboard obtainable under the International Load Line Regulations, the freeboard deck for the purpose of the Rules may be taken as the lowest actual deck from which the draft can be obtained under those regulations.

11.3 Bulkhead Deck

The bulkhead deck is the highest deck to which watertight bulkheads extend and are made effective.

11.5 Strength Deck

The strength deck is the deck which forms the top of the effective hull girder at any part of its length. See Section 3-2-1.

11.7 Superstructure Deck

A superstructure deck is a deck above the freeboard deck to which the side shell plating extends or of which the sides are fitted inboard of the hull side not more than 4% of the breadth, $B$. Except where otherwise specified, the term superstructure deck where used in these Rules refers to the first such deck above the freeboard deck.

13 Superstructure

A superstructure is an enclosed structure above the freeboard deck having side plating as an extension of the shell plating, or not fitted inboard of the hull side more than 4% of the breadth $B$.

15 Deckhouses

A deckhouse is an enclosed structure above the freeboard deck, having side plating set inboard of the hull side-shell plating more than 4% of the breadth $B$ of the craft.
17  **Displacement and Block Coefficient**

17.1  **Displacement**

The displacement $\Delta$, is the mass displacement of the craft in the design condition in metric tons (long tons), unless otherwise specifically noted.

17.3  **Block Coefficient ($C_b$)**

$C_b$ is the block coefficient obtained from the following equation:

$C_b = \frac{\Delta}{1.025 LBw l d}$  (SI & MKS units)

$C_b = \frac{35\Delta}{LBw l d}$  (US units)

where

$\Delta$ = molded displacement, as defined in 3-1-1/17.1
$L$ = scantling length, as defined in 3-1-1/3
$d$ = draft, as defined in 3-1-1/9
$B_{wl}$ = greatest molded breadth at the design load line

19  **Gross Tonnage**

The measurement of the internal volume of spaces within the craft as defined by the International Convention on Tonnage Measurement of Ships, 1969.

21  **Deadweight ($DWT$)**

For the purpose of these Rules, deadweight ($DWT$), is the difference, in metric tons (long tons), between the displacement of the craft at its summer load line or the craft with all tanks filled, maximum cargo loaded, maximum stores, and personnel or passengers and their effects on board, in water having a specific gravity of 1.025, and the unloaded weight of the craft. For the purpose of these Rules, the unloaded weight is the displacement of the craft, in metric tons (long tons), with no cargo, fuel, lubricating oil, ballast water, fresh water nor feed water in tanks, no consumable stores, and no personnel or passengers nor their effects.

23  **Significant Wave Height**

Significant wave height is the average height of the one-third highest observed wave heights over a given period.

25  **Speed**

Speed is the design speed in knots with the craft running ahead at the maximum continuous rated shaft rpm and at the summer load waterline. Operational speed is 90% of design speed.

27  **Rabbet Line (Fiber Reinforced Plastic)**

The rabbet line is the line intersection between the outside of a craft’s bottom and a craft’s keel. Where there is no keel, the rabbet line is the bottom of the craft.

29  **Administration**

The government of the state whose flag the craft is intended to fly.
31 **Passenger Craft**
Any craft which carries more than twelve passengers. See also 5-1-1/13.

33 **Cargo Craft**
Any craft other than a passenger craft, which is capable of maintaining the main functions of safety systems of unaffected spaces after damage in any one compartment on board. See also 1-2-2/1.

35 **Passenger**
A passenger is every person other than the master and members of the crew or other persons employed or engaged in any capacity on board a craft on the business of that craft, and a child under one year of age.

37 **Place of Refuge**
Any naturally or artificially sheltered area which may be used as shelter by a craft under conditions likely to endanger its safety.

39 **Crewboat**
A craft specifically fitted for the transferring/transporting of industrial personnel in the offshore oil and gas industry between a shore base facility and the offshore oil and offshore gas installations and vise versa. Crewboats may also carry cargo, however, are not considered as a Passenger Craft. See also Section 5-2-1.

39.1 **Industrial Personnel**
Every person carried onboard a Crewboat for the sole purpose of carrying out the business or functions of the offshore installations. See also Section 5-2-1.

41 **Fiber-Reinforced Plastic (FRP)**
FRP consists of two basic components: a glass-filament or other material fiber reinforcement and a plastic, or resin, in which the reinforcing material is imbedded.

41.1 **Reinforcement**
Reinforcement is a strong, inert material bonded into the plastic to improve its strength, stiffness and impact resistance. Reinforcements are usually fibers of glass (a lime-alumina-silicate composition having a low alkali content) or other approved material such as aramid or carbon fiber, in a woven or non-woven form, with a strong adhesive bond to the resin.

41.1.1 **Strand**
A bundle of continuous filaments combined in a single, compact unit.

41.1.2 **Roving**
A band or ribbon of parallel strands grouped together.

41.1.3 **Yarn**
A twisted strand or strands suitable for weaving into a fabric.

41.1.4 **Binder**
The agent applied in small quantities to bond the fibers in mat form.

41.1.5 **Coupling Agent**
An active water soluble chemical that allows resin to adhere to glass.
41.1.6 Chopped-strand Mat
A blanket of randomly oriented chopped-glass strands held together with binder.

41.1.7 Woven Roving
A coarse fabric woven from rovings.

41.1.8 Cloth
A fabric woven from yarn

41.1.9 Peel-Ply
An “E” glass fabric that does not have any coupling agent applied, used as a protective covering on a laminate being prepared for a secondary bond to keep foreign particles from adhering to the surface.

41.1.10 Uni-directional
A woven or non-woven reinforcement with substantially more fibers in one principal axis of the reinforcing ply.

41.1.11 Double Biased
A woven or non-woven reinforcement with fibers primarily at +45° to the principal axes of the reinforcing ply.

41.1.12 Knitted or Stitched Fabrics
Two or more layers of unidirectional fabrics that are stitched together.

41.1.13 Bi-axial Fabric
A stitched or knitted reinforcement with fibers primarily in the two principal axes of the reinforcing ply.

41.1.14 Tri-axial Fabric
A stitched or knitted reinforcement with fibers running in one principal axis of the ply and in addition, with fibers running at + and -45° to the warp.

41.1.15 Ply Principal Axes
The two principal axes of a reinforcing ply are the axis that is parallel to the warp and the axis that is parallel to the fill.

41.1.16 Warp
The roving or yarn running lengthwise in woven fabric (in the “roll direction”).

41.1.17 Fill, Weft or Woof
The roving or yarn running at right angles to the warp in a woven fabric.

41.1.18 "E" glass
A family of glass reinforcement material of aluminoborosilicate composition and having high electrical resistivity.

41.1.19 "S" glass
A family of glass reinforcement material of magnesium aluminosilicate composition that contains a higher silicon content and provides higher strength and stiffness properties than “E” glass.

41.1.20 Kevlar
An aramid fiber reinforcement.
41.1.21 Carbon Fiber
A reinforcement material made of mostly carbon produced by the pyrolysis of organic precursor fibers in an inert environment.

41.3 Resin
Resin is a highly reactive synthetic that in its initial stage is a liquid, but upon activation is transformed into a solid.

41.3.1 Accelerator
A material that, when mixed with a catalyst or resin, speeds the cure time.

41.3.2 Additive
A substance added to another substance, usually to improve properties, such as plasticizers, initiators, light stabilizers and flame retardants.

41.3.3 Catalyst or Initiator
A material that is used to activate resin, causing it to harden.

41.3.4 Crazing
Hairline cracks, either within or on the surface of resin, caused by mechanical or thermal stresses.

41.3.5 Cure
To change resin from a liquid to a solid.

41.3.6 Cure time
The time required for resin to change from a liquid to a solid after a catalyst has been added.

41.3.7 Exothermic Heat
The heat given off as the result of the action of a catalyst on resin.

41.3.8 Filler
A material added to resin to modify its working properties or other qualities, or to lower densities.

41.3.9 Gel
A partially cured resin in a semi-solid state similar to gelatin in consistency.

41.3.10 Gel Time
The time required to change a flowable, liquid resin into a nonflowing gel.

41.3.11 Inhibitor
A material that retards activation or initiation of resin, thus extending shelf life or influencing exothermic heat or gel time.

41.3.12 Polymerization
The reaction that takes place when resin is activated or initiated.

41.3.13 Pot Life
The length of time that a catalyzed resin remains workable.

41.3.14 Shelf Life
The length of time that an uncatalyzed resin maintains its working properties while stored in a tightly sealed, opaque container.
41.3.15 Tack
The degree of stickiness of the resin.

41.3.16 Thixotropy
The property or phenomenon, exhibited by some resins, of becoming jelly-like at rest but becoming fluid again when stirred or agitated. This facilitates the application of the resin to inclined or vertical surfaces.

41.3.17 Polyester Resin
A thermosetting resin that is formed by combining saturated and unsaturated organic acids. Such as orthophthalic and isophthalic acids.

41.3.18 Vinylester Resin
A thermosetting resin that consists of a polymer chain and an acrylate or methacrylate termination.

41.3.19 Epoxy
A resin that contains one or more of the epoxide groups.

41.5 Laminate
A laminate is a material composed of successive bonded layers, or plies, of resin and fiber or other reinforcing substances.

41.5.1 Bi-directional Laminate
A laminate having essentially the same strength and elastic properties in the two plane principal axes. Bi-directional laminates may be constructed of bi-axial, double bias, tri-axial, mat or unidirectional reinforcing layers, or a combination of any of these.

41.5.2 Uni-directional Laminate
A laminate with substantially more of the fibers in the plane of the laminate oriented in one of the two principal axis of the laminate plane so that the mechanical properties along that axis are appreciably higher than along the other natural axis.

41.5.3 Sandwich Laminate
A laminate consisting of two fiber reinforced plastic skins attached to a non-structural or structural core (see 3-1-1/41.7 “Encapsulation”).

41.5.4 Barcol Hardness
A measurement of the hardness of a laminate and thereby the degree of completion of the cure.

41.5.5 Delamination
The separation of the layers of material in a laminate.

41.5.6 Gel Coat
The first resin applied to mold when fabricating a laminate to provide a smooth protective surface for the laminate.

41.5.7 Layup
The process of applying to a mold the layers of resin and reinforcing materials that make up a laminate. These materials are then compressed or densified with a roller or squeegee to eliminate entrapped air and to spread resin evenly. Also a description of the component materials and geometry of a laminate.
41.5.8 Verified Minimum Mechanical Property
The mechanical properties, in Part 2, Chapter 6, of laminates differing from the basic, verified by the appropriate test(s) listed in 2-6-1/5.5 TABLE 1.

41.5.9 Laminate Principal Axes
The two principal axes of a square or rectangular plate panel are for the application of these Rules those perpendicular and parallel to the plate panel edges.

41.5.10 Vacuum Bagging
A method used to apply a uniform pressure over an area by applying a vacuum to that area.

41.5.11 Resin Impregnation
A process of construction for large layers of fabric that consists of running a roll of fabric through a resin bath to completely saturate the fabric.

41.5.12 Resin Transfer Molding
A closed mold method that mechanically pumps resin through dry fabric previously placed in the mold.

41.5.13 Resin Infusion
A method of FRP construction that uses a vacuum to pull catalyzed resin through dry fabric.

41.5.14 Primary Bond
The bond that is formed between two laminated surfaces when the resin on both surfaces has not yet cured.

41.5.15 Secondary Bond
The bond that is formed between two laminated surfaces when the resin on one of the two surfaces has cured.

41.5.16 Post Cure
The act of placing a laminate in an autoclave and raising the temperature to assist in the cure cycle of the resin.

41.5.17 Autoclave
A large oven used in post curing large laminated parts.

41.7 Encapsulation
The containment of a core material, such as softwoods, plywood, balsa, PVC (cross linked) or linear polymer, within FRP laminates. The cores may be structurally effective or ineffective.

41.7.1 Bedding Putty
Material used to adhere the core material to the FRP skins.

41.7.2 Scores
Slits cut into the core material to aid in forming the core to complex shapes.

43 Units
These Rules are written in three systems of units: SI units, MKS units and US customary units. Each system is to be used independently of any other system.

Unless indicated otherwise, the format of presentation in these Rules of the three systems of units is as follows:
SI units (MKS units, US customary units)
PART 3
CHAPTER 1 General
SECTION 2 General Requirements

1 Materials

These Rules are intended for welded craft constructed of steel, welded craft constructed of aluminum, and fiber reinforced plastic (FRP) craft; complying with the requirements of Part 2, Chapters 1 and 2, 5, and 6, respectively. The use of materials other than those specified in Part 2, Chapters 1, 2, 5, and 6 and the corresponding scantlings will be specially considered.

1.1 Selection of Material Grade

For craft 61 m (200 ft) and over in length, steel materials are not to be lower grades than those required by 3-1-2/1.1 TABLE 1 for the material class given in 3-1-2/1.1 TABLE 2 for the particular location.

</tbody>
</table>

Notes:
1. A radius gunwale plate may be considered to meet the requirements for both the stringer plate and the sheer strake, provided it extends suitable distances inboard and vertically. For formed material see 2-4-1/3.13.
2. Plating at the corners of large hatch openings are to be specially considered.
3. (2017) ASTM A36 steel otherwise manufactured by an ABS approved steel mill, t tested and certified to the satisfaction of ABS may be used in lieu of Grade A for thickness up to and including 12.5 mm (0.5 in.) for a plate and 19 mm (0.75 in.) for sections.
4. (1 July 2015) Steering equipment components other than rudders, as described in Section 3-2-8.

1.3 **Note for the Users**

The attention of users is drawn to the fact that when fatigue loading is present, the effective strength of higher-strength steel in a welded construction may not be greater than that of ordinary-strength steel. Precautions against corrosion fatigue to higher strength steel and aluminum alloy materials may also be necessary.

1.5 **Craft Exposed to Low Air Temperatures (1 July 2019)**

For craft intended to operate in areas with low air temperatures [below –10°C (14°F)], the materials in exposed structures are to be selected based on the design temperature \( t_D \), to be taken as defined in 3-1-2/1.7.
Materials in the various strength members above the lowest ballast water line (BWL) exposed to air (including the structural members covered by Note 5 of below TABLE 3) are not to be of lower grades than those corresponding to Classes I, II and III, as given in 3-1-2/1.5 TABLE 3, depending on the categories of structural members (secondary, primary and special). For non-exposed structures (except as indicated in Note 5 of 3-1-2/1.5 TABLE 3) and structures below the lowest ballast water line, 3-1-2/1.1 applies.

</tbody>
</table>

**Notes:**

1. Plating at corners of large hatch openings to be specially considered. Class III or Grade E/EH to be applied in positions where high local stresses may occur.
2. Not to be less than Grade E/EH within 0.4L amidships in craft with length exceeding 250 meters. (820 feet).
3. In craft with breadth exceeding 70 meters (230 feet) at least three deck strakes to be Class III.
4. Not to be less than Grade D/DH.
5. (2017) Applicable to plating attached to hull envelope plating exposed to low air temperature. At least one strake is to be considered in the same way as exposed plating and the strake width is to be at least 600 mm (24 in.).
The material grade requirements for hull members of each class depending on thickness and design temperature are defined in 3-1-2/1.5 TABLE 4. For design temperatures $t_D < -55^\circ C (-67^\circ F)$, materials are to be specially considered.

</tbody>
</table>
Single strakes required to be of Class III or of Grade E/EH or FH are to have breadths not less than $800 + 5L$ mm, maximum 1800 mm.

Plating materials for sternframes, rudder horns, rudders and shaft brackets are not to be of lower grades than those corresponding to the material classes given in 3-1-2/1.1.

1.7 Design Temperature $t_D$ (2017)

The design temperature $t_D$ is to be taken as the lowest mean daily average air temperature in the area of operation.

- *Mean:* Statistical mean over observation period (at least 20 years)
- *Average:* Average during one day and night
- *Lowest:* Lowest during year

For seasonally restricted service the lowest value within the period of operation applies.

For the purpose of issuing a Polar Ship Certificate in accordance with the Polar Code, the design temperature $t_D$ shall be no more than 13°C (23.6°F) higher than the Polar Service Temperature (PST) of the craft.

In the Polar Regions, the statistical mean over observation period is to be determined for a period of at least 10 years.

3-1-2/1.7 FIGURE 1 illustrates the temperature definition.

**FIGURE 1**

Commonly Used Definitions of Temperatures (2017)

![Graph showing temperature definitions with labels: MDHT = Mean Daily High (or maximum) Temperature, MDAT = Mean Daily Average Temperature, MDLT = Mean Daily Low (or minimum) Temperature.]

$MDHT$ = Mean Daily High (or maximum) Temperature

$MDAT$ = Mean Daily Average Temperature

$MDLT$ = Mean Daily Low (or minimum) Temperature
3 Workmanship

All workmanship is to be of commercial marine quality and acceptable to the Surveyor. Welding is to be in accordance with the requirements of Part 2, Chapter 4, Appendix 2-5-A1, Part 2, Chapter 14, and Section 3-2-13.

5 Design

5.1 Continuity

Care is to be taken to provide structural continuity. Changes in scantlings are to be gradual, such that the maximum angle from horizontal is 45°, see 3-1-2/5.1 FIGURE 2. Strength members are not to change direction abruptly, such that the maximum change in direction is 45°, see 3-1-2/5.1 FIGURE 3. Where primary structural members terminate at another structural member, tapering of the primary member or tapering brackets may be required beyond the other structural member, as indicated in 3-1-2/5.1 FIGURE 4, and as required in 3-2-5/1. Stanchions and bulkheads are to be aligned to provide support and to minimize eccentric loading. Major appendages outside the hull and strength bulkheads in superstructures are to be aligned with major structural members within the hull.

5.3 Openings

The structural arrangements and details are to be in accordance with Section 3-2-6. In general, major openings such as doors, hatches, and large vent ducts are to be avoided in the hull in close proximity to the gunwale. Corners of openings in strength structures are to have generous radii. Compensation may be required for openings.
5.5 Brackets

5.5.1 Steel Brackets

Where brackets are fitted having thicknesses as required by 3-1-2/5.5.2 TABLE 5A and faces at approximately 45 degrees with the bulkhead deck or shell, and the bracket is supported by a bulkhead, deck or shell structural member, the length of each member, $\ell$, may be measured at a point 25% of the extent of the bracket beyond the toe of the bracket as shown in 3-1-2/5.5.2 FIGURE 5. The minimum overlap of the bracket arm along the stiffener is not to be less than obtained from the following equation:

\[ x = 1.4y + 30 \text{ mm} \]
\[ x = 1.4y + 1.2 \text{ in.} \]

where

\[ x = \text{length of overlap along stiffener, in mm (in.)} \]
\[ y = \text{depth of stiffener, in mm (in.)} \]

Where a bracket laps a member, the amount of overlap generally is to be 25.5 mm (1 in.).

5.5.2 Aluminum Brackets

Aluminum brackets are to comply with 3-1-2/5.5.1 except that the thicknesses are given in 3-1-2/5.5.2 TABLE 5B.

### Structural Design Details

The designer is to give consideration to the following:

5.7.1 The thickness of internals in locations susceptible to rapid corrosion.

5.7.2 The proportions of built-up members to comply with established standards for buckling strength.

5.7.3 The design of structural details such as noted below, against the harmful effects of stress concentrations and notches:

- **i)** Details of the ends, the intersections of members and associated brackets.
- **ii)** Shape and location of air, drainage or lightening holes.
- **iii)** Shape and reinforcement of slots or cutouts for internals.
- **iv)** Elimination or closing of weld scallops in way of butts, “softening” of bracket toes, reducing abrupt changes of section or structural discontinuities.

5.7.4 Proportions and thickness of structural members to reduce fatigue response due to engine, propeller or wave-induced cyclic stresses, particularly for higher-strength steels.

Standard construction details based on the above considerations are to be indicated on the plans or in a booklet submitted for review and comment.

### Termination of Structural Members

Unless permitted elsewhere in these Rules, structural members are to be effectively connected to the adjacent structures in such a manner to avoid hard spots, notches and other harmful stress concentrations. Where members are lightly loaded and not required to be attached at their ends, special attention is to be given to the end taper, by using brackets or by a sniped end of not more than 30°. Bracket toes or sniped ends are to be kept within 25 mm (1.0 in.) of the adjacent member and the depth at the toe or snipe end is generally not to exceed 15 mm (0.60 in.). Where a strength deck or shell longitudinal terminates without end attachment, it is to extend into the adjacent transversely framed structure or stop at a local transverse member fitted at about one transverse frame space beyond the last floor or web that supports the longitudinal.

### Effective Width of Plating

The section modulus and moment of inertia of stiffening members are provided by the member and a portion of the plating to which it is attached. The effective width is as given in the following paragraphs. The section modulus and moment of inertia of a shape, bar, fabricated section, or laid-up member not attached to plating is that of the member only.
7.1 FRP Laminates

Where the plating is an FRP single-skin laminate, the maximum effective width of plating for floors, frames, beams and bulkhead stiffeners is not to exceed either the stiffening member spacing or the width obtained from the following equation, whichever is less. See 3-1-2/7.1 FIGURE 6.

\[ w = 18t + b \]

where:

- \( w \) = effective width of plating, in mm (in.)
- \( t \) = thickness of single skin plating, in mm (in.)
- \( b \) = net width of stiffening member, in mm (in.), but not more than \( 18t \)

Where the plating is an FRP sandwich laminate with a flexurally and compressively ineffective (balsa, cross linked PVC, or linear polymer) core, \( t \) in the above equation is the thickness of a single skin laminate having the same moment of inertia per unit width as the two skins of the sandwich about the neutral axis of the sandwich, excluding the core.

For a stiffening member along an opening, the maximum effective width of plating is equal to either one-half the stiffening member spacing or the width obtained from the following equation, whichever is less.

\[ w = 9t + b \]

where \( w \), \( t \) and \( b \) are as defined above.

7.3 Steel and Aluminum Plating

7.3.1 Primary Structural Members

The effective width of plating for deep supporting members is to be equal to the lesser of either one half the sum of spacing on each side of the member, 0.33 times the unsupported span, \( \ell \), or 750 mm (30 in.). For girders and webs along hatch openings, the effective width of plating is to be half of that obtained from the above. Due account is to be taken in regards to plate buckling, see 3-2-3/1.1.

7.3.2 All Other Structural Members

The maximum effective width of plating is equal to either one-half the sum of spacing on each side of the member or the width obtained from the following equation, whichever is less.
Steel Members \quad w = 80t
Aluminum Members \quad w = 60t

where

\begin{align*}
    w &= \text{effective width of plating, in mm (in.)} \\
    t &= \text{thickness of single skin plating, in mm (in.)}
\end{align*}

For a stiffening member along an opening, the maximum effective width of plating is one-half of the effective width given above.
This Section states requirements for a variety of direct analysis methods that can be used in lieu of or in conjunction with the specific requirements given in Sections 3-2-1, 3-2-2, 3-2-3, and 3-2-4 or to meet the requirements in 1-1-4/5. If the structure of the craft complies with 3-1-3/3.5, 3-1-3/5.3, 3-1-3/7.1.2, 3-1-3/7.3, 3-1-3/9.1, 3-1-3/9.3.3, and 3-1-3/11.3 of this section and the requirements in Sections 3-2-1, 3-2-2, 3-2-3, and 3-2-4 it will be eligible to receive the SH-DLA Class Notation. For guidance on the SH-DLA class notation not given in this Section, see the ABS Guidance Notes on Structural Direct Analysis for High-Speed Craft.

3 Loading Conditions

3.1 General

The loading conditions considered should include all intended operational conditions of the craft as specified by the Designer. These operating conditions are to be defined by significant wave height, wave period, and maximum operating speed. 3-1-3/3.1 TABLE 1 is to be used when the significant wave height is given in terms of Sea States. When the wave period is not given, the most probable modal period is to be used in the analysis.

</tr>
<tr>
<td>&gt;8</td>
<td>&gt;14 (45.9)</td>
</tr>
</tbody>
</table>

3.3 Environmental and Service Conditions

3.3.1 General

The environmental condition is anticipated to be described by appropriate sets of wave data. The sources and reliability of this data are to be submitted. The wave parameters used in the analysis are to be selected and documented based on the conditions given in the craft specification. If these
parameters are to be used in conjunction with the requirements in 3-1-3/3.5, 3-1-3/5.3, 3-1-3/7.1.2, 3-1-3/7.3, 3-1-3/9.1, 3-1-3/9.3.3, and 3-1-3/11.3, then they should be compatible with the stochastic response and extreme value prediction methods.

3.3.2 Types of Wave Spectra
3.3.2(a) Deep-water Ocean Waves.
Deep-water Ocean Waves. Two-parameter spectra, such as the Bretschneider or PM wave spectral formulations, are to be used. If the swell and wave components are known to interact, a bi-modal Ochi-Hubble spectrum is to be used. Directional spreading appropriate to coastal conditions is also to be applied.

3.3.2(b) Shallow-water Waves.
Wave conditions that include the effects of bathymetry, wind field, coastal contours of the region are to be used. For fetch-limited sea conditions, JONSWAP spectrum or a modified version of the spectrum is to be used.

3.5 Loading Conditions for Direct Analysis
3.5.1 Dominant Load Parameters
A list of Dominant Load Parameters (DLP) is to be developed. This will include select motion and load effect parameters. Other loads, such as those due to wave impacts on the bow and stern, flare and bottom slamming, wet-deck slamming (multi-hulls) and vibration effects on local structural strength, have to be treated separately. Considerations for slamming analysis are given in 3-1-3/3.5.7.

3.5.2 Load Cases
Load cases are defined by a combination of craft loading conditions, a set of global motion and load effect parameters set forth in terms of each of the DLPs, other load components accompanying the DLPs and an equivalent wave system for the specified DLP. Justification for load cases selected for use in the structural analysis is to be submitted to ABS for review.

3.5.3 Analyses of Ship Motions, Wave Loads, and Extreme Values
Calculations are to be made using the spectral analysis-based approach, which by definition relies on the use of Response Amplitude Operators (RAOs). Each RAO is to be calculated for regular waves of unit amplitude for a range of wave frequencies and wave headings that will be given below.

3.5.4 Essential Features of Spectral Analysis of Motions and Loads
3.5.4(a) General Modeling Considerations.
The model of the hull should include the masses of all equipment, vehicles and supporting structure. There is also to be sufficient compatibility between the hydrodynamic and structural models so that the application of fluid pressures onto the finite element mesh of the structural model can be done appropriately.

For the load component types and structural responses of primary interest, software formulations derived from linear idealizations are deemed to be sufficient. The capabilities and limitations of the software are to be known, and in cases where the software is not known to ABS, it may be necessary to demonstrate the adequacy of the software.

3.5.4(b) Diffraction-Radiation Methods.
Computations of the wave-induced motions and loads are to be carried out through the application of seakeeping analysis codes utilizing three-dimensional potential flow based diffraction-radiation theory. Computation of the hydrodynamic pressures should take account of, as a minimum, all six degree-of-freedom rigid-body motions of the hull. These codes may be based either on linear
(small) wave and motion amplitude assumptions or nonlinear (large) amplitude motion and wave formulations.

3.5.4(c) Panel Model Development.
The Rankine source panel method is recommended for solving the hydrodynamic boundary value problem.

3.5.4(d) Motion and Load-Effect Response Amplitude Operators.
For each loading condition, RAOs of all the selected DLPs are to be calculated. The RAOs are to represent the pertinent range of wave headings (β), in increments not exceeding 15 degrees. A range of wave frequencies is to be considered based on the route-specific wave conditions (see 3-1-3/3.3). The nominal range is 0.2 rad/s to 1.8 rad/s in increments of 0.05 rad/s.

The worst frequency-heading (ω, β) combination is to be determined from an examination of the RAOs for each DLP. Only the heading β_max and the wave frequency ω_e at which the RAO of the DLP is a maximum, need to be used in DLA or direct analysis.

3.5.5 Extreme Values Analysis
Extreme value analysis is to be performed for each DLP to determine the maximum values. An extreme value method that follows the so-called long-term approach is to be used. The use of a validated short-term extreme value approach, which is appropriate to the craft type and route-specific environmental data, will also be considered. The supplementary use of such a short-term approach to confirm or test the sensitivity of the long-term based design values is recommended.

The relevant value to be obtained from the long-term response analysis is the most probable extreme value (MPEV) having a probability of level of 10^-8 in terms of wave encounters.

3.5.6 Equivalent Wave
For each load case, an equivalent wave is to be determined which simulates the magnitude and location of the extreme value of the dominant load component of the load case.

The amplitude of the equivalent wave is to be determined using the extreme values of the DLP (see 3-1-3/3.5.4) and the RAO of that DLP occurring at the wave frequency and wave heading corresponding to the maximum amplitude (peak) of the RAO. The amplitude of the equivalent wave is given by:

\[ a_{wj} = \frac{MPEV_j}{MaxRAO_j} \]

where

\[ a_{wj} = \text{wave amplitude} \]

\[ MPEV_j = \text{Most Probable Extreme Value of the } j^{th} \text{ DLP at a probability level equivalent to the design criterion} \]

\[ MaxRAO_j = \text{maximum amplitude of the } j^{th} \text{ DLP’s RAO} \]

3.5.7 Slamming Loads
Loads due to slamming and wave impact on craft hulls are categorized into global slamming effects and local slam-induced structural response.

3.5.7(a) Global Slamming Effects.
The simplified formulae given in Section 3-2-1 may be used to account for global slamming effects in the preliminary design stage. For detailed analysis, a direct time-domain simulation
involving short-term predictions are to be used for the global strength assessment of monohulls. In most cases involving high speeds, the absolute motions or relative motions will be of such large amplitude that nonlinear calculations will be required. In catamarans, wet deck slam-induced global whipping effects of the hull is to be assessed using methods that account for coupling of the symmetric and anti-symmetric modes of responses. These calculations will require time-domain analysis methods.

3.5.7(b) Local Impact Loads.
Panel structures with horizontal flat or nearly flat surfaces such as a wet deck of a multi-hull craft will need to be hydroelastically modeled, where in the dynamics of the fluid and the elastic response of the plate and stiffeners are simultaneously modeled.

5 Motion Predictions

5.1 Model Testing
Craft hull motions and accelerations obtained from scale model tests may be used to validate motions predicted by computer programs. Model testing is required to be performed and reported to ABS when loads are being submitted in lieu of the loads determined in Section 3-2-2 or other loads determined by ABS. The model is to accurately represent the structure that is to be built in both principal particulars and hull geometry.

5.1.1 Testing Program
The model is to be tested over a range of speeds, headings, and wave characteristics (height, length, and period), as indicated by ABS. When this is not specified, the testing program is to include the following:

5.1.1(a) Speeds. The model is to be tested at the minimum speed required by ABS and the maximum achievable speed of the craft for a particular wave profile and heading.

5.1.1(b) Headings. The model is to be tested in head, beam, quartering, and following seas.

5.1.1(c) Wave Parameters. The model is to be tested in both deep water and shallow water wave conditions. These are defined in 3-1-3/3.3.2. For craft that are limited to operation in coastal regions (Coastal Craft and Riverine Craft), deep water wave profile testing is not required.

5.1.2 Model Measurements and Reporting
The parameters listed below are to be measured and reported based on the model test program. Some of the parameters listed may be derived through statistical analysis of measured data obtained from testing. When statistical analysis is used, the methods of analysis employed are to be indicated in the report.

5.1.2(a) Vertical or Heave Acceleration.
The significant, $\frac{1}{10}^{th}$ highest, or $\frac{1}{100}^{th}$ highest vertical acceleration at the longitudinal center of gravity, bow, and stern are to be reported. The accelerometer is to be adjusted such that the acceleration due to gravity is not measured. The $\frac{1}{100}^{th}$ highest vertical acceleration at the longitudinal center of gravity may be used in place of $n_{cg}$ in 3-2-2/1 and 3-2-2/3.

5.1.2(b) Roll Acceleration.
The significant roll acceleration about a longitudinal axis through the center of gravity and the maximum roll angle are to be reported.

5.1.2(c) Pitch Angle and Acceleration.
The significant coupled pitch-and-heave acceleration at the bow and the stern and the maximum pitch angle are to be reported.
5.3 Accelerations from Direct Analysis

5.3.1 General
The wave-induced craft motions may be determined by direct analysis. When this analysis is not performed by ABS, it is to be verified by model testing as indicated in 3-1-3/5.3.

5.3.2 Global Accelerations
Global accelerations are to be determined using the loading conditions indicated in 3-1-3/3.5 above. The \( \frac{1}{100} \) highest vertical (heave) acceleration at the longitudinal center of gravity may be used in place of \( n_{cg} \) in Section 3-2-1 and Section 3-2-2.

5.3.3 Local Accelerations
Local accelerations at points where the lightship weight of the structure, (non-liquid cargo), are located, including deck-mounted equipment, should be calculated to determine the inertia loads. For vehicle decks, wheel loading should be applied. An evenly distributed load equivalent to the weight of the vehicles may be used. The acceleration RAO at a location of interest is to be calculated to account for all translational and rotational components of motions.

The components of the gravitational acceleration in the craft’s coordinate system are to be included.

7 Load Predictions

7.1 Global Loads
As a minimum, the still-water hogging and sagging moments and shear forces, the wave-induced hogging and sagging moments and shear forces and the slam-induced moments and shear force, are to be determined for monohull craft. Multi-hulled craft are to have the transverse bending moment, the torsional (or pitch connecting) moment and the transverse shear force determined in addition to the moments and shear forces determined for monohull craft. These loads are to be reported so that they can be used in conjunction with the requirements in 3-1-3/9 or Section 3-2-1.

7.1.1 Computation of Global Load Effects

7.1.1(a) Still-water Bending Moment and Shear Force.
The still-water bending moments and shear forces are to be calculated in the light load, half load, and full load conditions. The light load condition consists of all components of the craft (structure, machinery, piping equipment, outfitting, wiring, interiors, paint, etc.) plus 10% of tank and cargo capacity. The half load condition is to include all components of the craft plus 50% of the tank and cargo capacity. The full load condition consists of all components of the craft plus 100% of the tank and cargo capacity. The distribution of the load is to capture all major weight discontinuities, and no single weight distribution segment is to be greater than 0.20L.

7.1.1(b) Wave-Induced Longitudinal Bending Moment and Shear Force.
The wave-induced bending moments and shear forces can be determined by using the environmental conditions outlined in 3-1-3/3.3.

7.1.1(c) Transverse Bending Moment and Shear Force – Multi-hulled Craft.
The transverse bending moment and shear force may be determined by distributing the weights and loads athwartships across the craft and using the environmental conditions outlined in 3-1-3/3.3

7.1.1(d) Torsion Bending Moment.
The torsional bending moment may be determined by distributing the weights and loads on segments of the hull sliced at a 45° angle from centerline and using the environmental conditions outlined in 3-1-3/3.3.
7.1.1 Slamming Induced Bending Moment and Shear Force.
The slam induced bending moment and shear force may be calculated by applying the acceleration determined in 3-1-3/5 or in 3-2-2/1 to the lumped masses developed for 3-1-3/7.1.1(a).

7.1.2 Global Loads from Computations
Global loads from computer software programs are to be developed by loading the structure as outlined in 3-1-3/3.5. The computer program is to be capable of determining the moments and shear forces in 3-1-3/7.1 or developing loads that can be used in conjunction with finite element methods as outlined in 3-1-3/9.1.

7.3 Local Loads
Loads that differ from the pressure loads developed in Section 3-2-2 may be used to determine the required scantlings in conjunction with the requirements in 3-1-3/9.3 or Section 3-2-3 and Section 3-2-4. These loads are to be developed under the loading conditions in 3-1-3/3 and the following subparagraphs.

7.3.1 External Hydrodynamic Pressure
The hydrodynamic pressures at selected points on the external contours of the hull sections, are to be calculated in regular waves.

7.3.1(a) External Pressure Components.
The total hydrodynamic pressure is to include the pressure components due to waves and the components due to craft motion. Components of the hydrodynamic pressure are to be calculated from the panel model analysis of 3-1-3/3.5.3.

7.3.1(b) Pressures Accompanying the Dominant Load Parameter and Their Distribution.
The external pressure is to be calculated either as a complex number or in terms of the amplitude and phase. Then, ‘simultaneously’ acting pressures over the wetted surface can be represented in the form:

\[ P = (A)(a_w)\sin(\omega_e t + \epsilon_I) \]

where

- \( P \) = simultaneous pressure
- \( A \) = amplitude of the pressure RAO
- \( a_w \) = equivalent wave amplitude
- \( \omega_e \) = frequency of the equivalent wave when the RAO of the dominant load component of the load case reaches its maximum
- \( t \) = time under consideration.
- \( \epsilon_I \) = phase angle of the (other) load component’s RAO

7.3.1(c) Pressure Loading for Finite Element Models.
The hydrodynamic pressure can be linearly interpolated to obtain the nodal pressures for the finite element models required for structural analysis.

7.3.1(d) Pressure Loading for Rule Requirements.
For pressures that are to be used in conjunction with the requirements in Section 3-2-3 and Section 3-2-4 for determining the local scantlings, the hydrodynamic pressures are to be resolved into kN/m² (tf/m², psi).
7.3.2 Internal Tank Pressure

Liquid pressures in the cargo tanks are to be calculated and applied to the structural model used in finite element analysis. Both static and dynamic pressures should be included in the analysis, assuming that there is no relative motion between the tank and the contained fluid.

7.3.2(a) Pressure Components.

The internal tank pressure is to account for both the quasi-static and motion-induced (dynamic) pressure components. The quasi-static component results from gravity and should include craft roll and pitch rotations. The dynamic component is to be developed from the accelerations in the liquid at the tank boundary caused by the hull’s motions in six degrees of freedom. These are to be obtained from motion analysis as specified in 3-1-3/3.

The total instantaneous internal tank pressure for each of the tank boundary points is to be calculated by combining the inertial and quasi-static components as follows:

\[ p = p_o + \rho h_t \left[ \left( g_x + a_x \right)^2 + \left( g_y + a_y \right)^2 + \left( g_z + a_z \right)^2 \right]^{1/2} \]

where

- \( p \) = total instantaneous internal tank pressure at a tank boundary point
- \( p_o \) = vapor pressure or the relief valve pressure setting
- \( \rho \) = fluid density, cargo or ballast
- \( h_t \) = total pressure head defined by the height of the projected fluid column in the direction of the total instantaneous acceleration vector
- \( a_{x,y,z} \) = longitudinal, lateral, and vertical wave-induced accelerations relative to the craft’s axis system at a point on a tank’s boundary
- \( g_{x,y,z} \) = longitudinal, lateral, and vertical components of gravitational accelerations relative to the craft’s axis system at a tank boundary point

7.3.2(b) Roll and Pitch Motions.

The influence of ship motions on tank pressures is to be taken into account using the maximum pitch and roll angles. As reflected in the previous formulations, the inclination of the tank due to craft roll and pitch is to be considered in the calculation of the hydrostatic pressure. The direction of gravitational forces in the ship-fixed coordinate system varies with roll and pitch, resulting in a change in pressure head and a corresponding change in the static pressure.

7.3.2(c) Simultaneously Acting Tank Pressure.

At each wave condition, for each load case described in 3-1-3/3.5, simultaneously acting tank pressures (quasi-static and dynamic) are to be calculated. Each wave condition is defined by wave amplitude, frequency, heading angle and wave crest position, as explained in 3-1-3/3.5. Using the wave amplitude and phase angle determined based on the RAO of a DLP, the simultaneously acting tank pressure is to be calculated for the instant when the maximum value of the DLP occurs. These internal tank pressures are to be used in the structural finite element model.

7.3.3 Inertia Force of Lumped Structural Mass

The inertia force, or point load, of a structural mass, such as deck equipment or cargo, can be determined by the following equation:

\[ F = m(A_t) \]

where
\[ F = \text{inertial load of the item} \]
\[ m = \text{mass of the lumped weight of the structural member} \]
\[ A_t = \text{amplitude of the acceleration RAO} \]

For finite element models, the inertia forces in three (global) directions are to be calculated and applied. For a first-principles analysis, the inertia force in the vertical direction is to be calculated and applied.

9 Structural Response

9.1 Global Response

The global bending moments developed in 3-1-3/7.1 can either be applied to the requirements in 3-2-1/1.1.2(e), 3-2-1/1.5, 3-2-1/1.9.4, and 3-2-1/3.5 or to a global finite element model as outlined in this paragraph.

9.1.1 General

The load cases of 3-1-3/3.5 are to be applied to the global structural analysis model described in 3-1-3/9.1.4. Each load case is to include the hydrostatic and still-water load components that have not otherwise been directly included in the load component determination performed in accordance with 3-1-3/7.3.1 and 3-1-3/7.3.3. These hydrostatic or still-water components are to be included in the hydrostatics analysis.

9.1.2 Equilibrium Check

The model of the hull girder structure should be close to equilibrium when all the loads (static and dynamic) are applied.

The unbalanced forces in the model’s global axis system for each load case need to be determined and resolved. The magnitudes of the unbalanced forces, and the procedure used to balance the structural model in equilibrium is to be fully documented.

9.1.3 General Modeling Considerations

To the maximum extent practicable, the overall model of the hull structure should be comprised of the entire hull. There is also to be sufficient compatibility between the hydrodynamic and structural models so that the application of fluid pressures onto the finite element mesh of the structural model can be done appropriately.

For the load component types and structural responses of primary interest, analysis software formulations derived from linear idealizations are sufficient. Enhanced bases of analysis may be required so that non-linear loads, such as hull slamming, may be required. The adequacy of the selected software is to be demonstrated to the satisfaction of ABS.

The results of overall (global) model analysis are to be directly employed in the creation and analysis of the required finer mesh, local structural models. Appropriate boundary conditions determined in the larger scale model are to be imposed in the local models to assure appropriate structural continuity and load transfer between the various levels of models.

9.1.4 Analysis of the Global Hull Structure

The global structural and load model is to be as detailed and complete as possible. The stress results of the global model are used only to assess the hull girder plating of the deck (and wet deck for multi-hulled craft), side shell, bottom, inner bottom, longitudinal bulkheads, transverse bulkheads and stools or deck box girders. The main supporting members of the hull girder may be evaluated using 2-D fine-mesh local models. In developing the 3-D global finite element model, the following requirements apply:
The finite element model is to include all primary load-carrying members. Secondary structural members which may affect the overall load distribution are also to be included.

Structural idealization is to be based on the stiffness and anticipated response of the structure, not wholly on the geometry of the structure itself.

The relative stiffness between associated structural members and their anticipated response under the specified loading is to be considered.

A judicious selection of nodes, elements, and degrees of freedom is to be made to represent the stiffness and mass properties of the hull, while keeping the size of the model and required data generation within manageable limits. Lump of plating stiffeners, use of equivalent plate thickness, and other techniques may be used for this purpose.

The finite elements, whose geometry, configuration, and stiffness closely approximate the actual structure, can typically be of three types:

- Truss or bar elements with axial stiffness only
- Beam elements with axial, shear, and bending stiffness
- Membrane plate elements, either triangular or quadrilateral.

When possible, the finite element structure is to be based on the use of gross or as-built scantlings.

9.3 Local Response

The local loads developed in 3-1-3/7.3 may be used in conjunction with the scantling requirements in Section 3-2-3 and Section 3-2-4. For local structure that forms a grillage, or that is arranged in a manner not indicative of the principles given in the other Sections of these Rules, or structure that is being examined in conjunction with a finite element analysis may be reviewed using the following:

9.3.1 Non-Prismatic Beam Analysis

Beams that do not have uniform cross-sections may be analyzed using a non-prismatic beam program. The adequacy of the selected software is to be demonstrated to the satisfaction of ABS. In developing the non-prismatic beam model, the following requirements apply:

- The program is to be capable of calculating the shear and bending moment at all locations along the length of the beam.
- Section properties of the beam are to be inputted into the program to resemble the actual construction of the beam and are to have a maximum segment length of 300 mm (1 foot).
- The loads for the beam may be derived from Section 3-2-2 or 3-1-3/7.
- The boundary conditions of the beam are to reflect the structural arrangement.

9.3.2 Grillage or Plane Frame Analysis

Structure that forms a grillage, or an area of structure that is arranged in a manner that is different from the principles of these Rules, may be analyzed using a grillage or plane frame analysis program. The adequacy of the selected software is to be demonstrated to the satisfaction of ABS. In developing the grillage or plane frame model, the following requirements apply:

- The beam elements in the model are to be arranged to reflect all of the structure in the area under consideration.
- The program is to be capable of applying off-axis loads to the elements and nodes.
- The program is to be capable of calculating and reporting the bending moments and shear forces at each node.
- The loads for the model may be derived from Section 3-2-2 or 3-1-3/7.
v) The boundary conditions of the model are to reflect the structural arrangement. Boundary conditions that model symmetry will be specially considered.

9.3.3 Local Fine Mesh Model from Global 3-D Model

Detailed local stresses are to be determined by fine mesh FEM analysis of local structures, based on the results of the global 3-D analysis.

The requirements for developing the 3-D coarse mesh global model in 3-1-3/9.3.4 are also applicable to the development of the 2-D fine-mesh models. In developing the 2-D fine mesh model, the following requirements apply:

i) The mesh size of the 2-D finite element model are to be determined by adequately modeling the stiffness of the individual structural members forming the local structure.

ii) In modeling a local transverse structure, the web plating is modeled by membrane plates, using both quadrilateral and triangular elements. Stiffeners on the web plating, such as panel breakers, tripping brackets, flat bar stiffeners, etc., and the face plates of the webs are modeled by rod elements of equivalent cross sectional areas. Where face plates on brackets are tapered at the ends, the area of the rod elements should be reduced accordingly. The out-of-plane hull girder plating (i.e., deck, side shell, bottom shell, girders, etc.) is also to be modeled by rod elements, using an appropriate effective width.

iii) The mesh size used should be adequate to represent the overall stiffness of the considered local structure as a whole, such that smooth stress distributions in the structure can be obtained.

iv) Finer meshes are to be used in the probable high stressed areas in order to obtain more accurate stress distributions for these areas. The use of a uniform mesh with smooth transition and with avoidance to abrupt changes in mesh sizes is recommended.

v) In laying out the mesh, the shapes of membrane elements created are to be as regular as possible. The aspect ratios of plate elements are to be kept within 2:1. Elements with an aspect ratio higher than 5:1 may be used for convenience of modeling in way of low stress areas, or areas of low interest.

vi) The grid line spacing and element sizes for the transverse section can be determined by the spacing of the longitudinals on the bottom shell, inner bottom, and topside tank. The grid lines can either be in line with the longitudinals, or for a finer mesh, an additional one division can be added between the longitudinal spacing.

vii) Cutout openings for longitudinals and access holes need not be considered in the 2-D models. This is also applies to all lightening holes or other small openings in the webs.

viii) The stiffeners, panel breakers, and ribs that prevent local buckling that are parallel to the principal direction of stress are to be included in the model.

Boundary displacements obtained from the 3-D global analysis are to be used as boundary conditions in the fine mesh analysis. As applicable, the fine mesh models are to include at least the following local structures:

- A number of transverse web frames
- Centerline longitudinal girder
- Side longitudinal girder
- Horizontal stringers of watertight transverse bulkhead
- Other areas of high stress indicated from the 3-D global analysis.

Where the 3-D global analysis is not comprehensive enough to determine adequately the total stress in the longitudinal plating (e.g., deck and shell) and transverse bulkhead plating of the craft,
additional analyses may be required. Such analyses may not require the performance of fine mesh
FEM analysis, where the needed results can be provided by another acceptable method.

9.3.4 Local Fine Mesh Model without Global 3-D Model

Structure that forms a grillage or an area of structure that is arranged in a manner different from
the principles of these Rules may be analyzed using a local finite element model. The adequacy of
the selected software is to be demonstrated to the satisfaction of ABS. In developing the local
finite element model, the following requirements apply:

i) The requirements in 3-1-3/9.3.4 are to be applied as applicable.

ii) The loads for the model may be derived from Section 3-2-2 or 3-1-3/7.

iii) The boundary conditions of the model are to reflect the structural arrangement. Boundary
conditions that model symmetry will be specially considered.

11 Structural Acceptability

11.1 Beam, Grillage, or Plane Frame Analysis

The allowable bending stress for elements in beam, grillage or plane frame models is given in 3-2-4/1.3.1
TABLE 1 or 3-2-4/7 TABLE 2. The allowable shear stress for aluminum and steel elements is $0.5\tau_y$
($0.75\tau_y$ for bottom primary structures) where $\tau_y$ is the minimum shear yield strength of the material. For
aluminum structure, $\tau_y$ is to be in the welded condition. The allowable shear stress for composite members
is $0.4\tau_u$, where $\tau_u$ is the lesser of the ultimate shear strength in either the warp or fill of the web laminate.

11.3 Finite Element Analysis

11.3.1 General

The adequacy of the finite element analysis results is to be assessed for the failure modes of
material yielding and buckling. The requirements in this section are for steel, aluminum and FRP
craft. The acceptance criteria for craft constructed of other materials will be specially considered.

11.3.2 Yielding

For a plate element subjected to biaxial stress, a specific combination of stress components, rather
than a single maximum normal stress component constitutes the limiting condition. In this regard,
the total equivalent stress is to be based on the Hencky von-Mises criterion as the following
equation:

$$\sigma_e = \left[\sigma_x^2 + \sigma_y^2 - \sigma_x\sigma_y + 3\tau_{xy}^2\right]^{1/2}$$

where

$$\sigma_x = \text{normal stress in the } x \text{ coordinate direction of the element}$$

$$\sigma_y = \text{normal stress in the } y \text{ coordinate direction of the element}$$

$$\tau_{xy} = \text{in-plane shearing stress}$$

The total equivalent stress (Hencky von-Mises stress) is to be less than or equal to the following
design stress:

Steel: $0.95\sigma_y$
Aluminum: $0.85\sigma_y$
FRP: $0.37\sigma_u$
where $\sigma_y$ is the yield strength for steel structures or the welded yield strength for aluminum structure, and $\sigma_u$ is the ultimate tensile or compressive strength of the laminate, whichever is less.

Component stresses ($\sigma_x, \sigma_y, \tau_{xy}$) are to be less than or equal to allowable local structure design stress.

### 11.3.3 Design Global Hull Girder Stresses

The design stresses are as follows:

- **Global Longitudinal Strength of All Hull Types**
  \[
  \sigma_a = \text{design longitudinal bending stress, } \frac{f_p}{CQ} \text{ N/mm}^2 (\text{kgf/mm}^2, \text{psi})
  \]
  \[
  \tau_a = \text{design shear stress, } \frac{110}{Q} \text{ N/mm}^2 (1.122/Q \text{ tf/cm}^2, 7.122/Q \text{ Ltf/in}^2)
  \]
  \[
  f_p = 17.5 \text{ kN/cm}^2 (1.784 \text{ tf/cm}^2, 11.33 \text{ Ltf/in}^2)
  \]
  \[
  C = 1.0 \quad \text{for steel craft}
  \]
  \[
  = 0.90 \quad \text{for aluminum craft}
  \]
  \[
  = 0.80 \quad \text{for fiber-reinforced plastic craft}
  \]
  \[
  Q \text{ for steel:}
  \]
  \[
  = 1.0 \quad \text{for ordinary strength steel}
  \]
  \[
  = 0.78 \quad \text{for grade H32 steel}
  \]
  \[
  = 0.72 \quad \text{for grade H36 steel}
  \]
  \[
  Q \text{ for aluminum:}
  \]
  \[
  = 0.9 + q_5 \text{ but not less than } Q_o
  \]
  \[
  q_5 = \frac{115}{\sigma_y} (12/\sigma_y, 17000/\sigma_y)
  \]
  \[
  Q_o = \frac{635}{(\sigma_y + \sigma_u)} [65/(\sigma_y + \sigma_u), 92000/(\sigma_y + \sigma_u)]
  \]
  \[
  \sigma_y = \text{minimum yield strength of unwelded aluminum in N/mm}^2 (\text{kgf/mm}^2, \text{psi}) \text{ (not to be greater than } 0.7\sigma_u)
  \]
  \[
  \sigma_u = \text{minimum ultimate strength of welded aluminum in N/mm}^2 (\text{kgf/mm}^2, \text{psi})
  \]
  \[
  Q \text{ for fiber reinforced plastic:}
  \]
  \[
  = \frac{400}{0.75\sigma_u} (41/0.75\sigma_u, 58000/0.75\sigma_u)
  \]
  \[
  \sigma_u = \text{minimum ultimate tensile or compressive strength, whichever is less, verified by approved test results, in N/mm}^2 (\text{kgf/mm}^2, \text{psi}). \text{ See Section 2-6-5. Strength properties in the longitudinal direction of the craft are to be used.}
  \]

- **Global Transverse Strength of Multihulls**
  \[
  \sigma_a = \text{design transverse bending stress, } 0.66\sigma_y \text{ for aluminum and steel craft and } 0.33\sigma_u \text{ for FRP craft, in N/mm}^2 (\text{kgf/mm}^2, \text{psi})
  \]
  \[
  \sigma_{ab} = \text{design torsional or combined stress, } 0.75\sigma_y \text{ for aluminum and steel craft and } 0.367 \sigma_u \text{ for FRP craft, in N/mm}^2 (\text{kgf/mm}^2, \text{psi})
  \]
  \[
  \tau_a = \text{design transverse shear stress, } 0.38\sigma_y \text{ for aluminum and steel craft and } 0.40\tau_u \text{ for FRP craft, in N/mm}^2 (\text{kgf/mm}^2, \text{psi})
  \]
\[ \sigma_y = \text{minimum yield strength of the material, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)}. \text{ For aluminum the yield strength is to be for the unwelded condition and not to be greater than 0.7} \]

\[ \sigma_u = \text{minimum tensile or compressive strength, whichever is less, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)} \]

\[ \sigma_{uw} = \text{ultimate tensile strength of material in the welded condition, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)} \]

\[ \delta_m = \text{maximum deflection for FRP craft, } (\sigma_a/E) L_I, \text{ in m (in.)} \]

\[ \tau_u = \text{minimum ultimate through thickness shear strength, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)} \]

\[ L_I = \text{mean span of cross structure, in cm (in.), as indicated in 3-2-A2/3 FIGURE 2} \]

\[ E = \text{tensile or compressive modulus of the FRP laminate, whichever is lesser, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)} \]
PART 3

CHAPTER 1 General

SECTION 4 Guide for Finite Element Analysis

1 General

The intent of this section is to provide guidance on the use of finite element methods (FEM) for evaluating linear response of hull structural components, equipment foundations and reinforcement structure to applied loads.

Finite element methods can be applied with varying level of detail and complexity to determine stress levels, deflection magnitudes and other parameters of structural components. The choice of the type of finite element and evaluation criteria should match the desired level of detail, loading scenario, boundary conditions and complexity of the structural component.

3 Structural Modeling

3.1 Finite Element Types

The choice of the type of finite element is guided by the complexity of the structural system or component being analyzed, the level of detail desired and the outcomes measured. Two node line element and three or four membrane/plate element are considered sufficient for representation of a structure and requirements in this appendix assumes the use of such element types in the models. Higher order elements may also be applied. Details of basic element types are given in 3-1-4/3.1 TABLE 1.

<table>
<thead>
<tr>
<th>Finite Element Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rod (or truss) element</td>
<td>Line element with axial stiffness only and constant cross-sectional area along length of the element</td>
</tr>
<tr>
<td>Beam element</td>
<td>Line element with axial, torsional and bi-directional shear and bending stiffness and with constant properties along the length of the element</td>
</tr>
<tr>
<td>Membrane (or plane-stress) element</td>
<td>Plate element with in-plane stiffness and with constant thickness</td>
</tr>
<tr>
<td>Shell (or bending plate) element</td>
<td>Plate element with in-plane and out-of-plane bending stiffness and with constant thickness</td>
</tr>
</tbody>
</table>

3.3 Model Types

3.3.1 Beam/Grillage Model

Beam/grillage models comprise of entirely of beam and rod elements, and are suitable for the solution of simple to more elaborate beam problems of one, two or three-dimensional configuration. Examples where such models could be applied are for deck beams, girders, floors, and bulkhead stiffening. Such models provide bending moment and shear force distributions, axial, bending and shear stresses, and deflection magnitudes.
3.3.2 Plate Element Model

Plate element models are applied in cases where a precise representation of the geometry of the structural component or system is necessary, the complexity of the structure warrants it, or when the desired structural response cannot be determined from beam or grillage models.

3.5 Modeling Guidance

i) The model should include, as applicable, all primary load-carrying members of the structure being analyzed. Secondary structural members that may significantly affect load distributions and local response of the primary members may also be appropriately included in the model.

ii) For beam elements, cross sectional properties are to be based on that of effective width of the attached plating. The effective width of plating of beam elements is not to exceed the sum of one-half of the spacing on either side of the structural member or \( \frac{1}{3} \) of the unsupported span of the member, whichever is less.

iii) Plate element meshing is to follow the stiffening system as far as practicable. The mesh size used should be adequate to represent the overall stiffness of the considered structure. For meshing of large systems such as deck, shell or bulkhead plate/framing systems, the mesh size is to not exceed the spacing between the frames. The mesh should be progressively and smoothly refined to capture structural details where important or found necessary.

iv) At least three elements are to be used, where practical, to model webs of primary supporting members such as girders, transverses, stringers and floors. Rod elements may be used to model flanges of primary supporting members and brackets. The cross sectional area of rods representing sniped or tapered flanges is to be considered proportionally using an average area over the length of the element.

v) The aspect ratio of plate elements, in general, is not to exceed three. The use of triangular plate elements is to be kept to a minimum.

vi) Shell elements are to be used for plate elements subjected to lateral loading.

3.7 Boundary Conditions

Boundary conditions applied are to reflect, as closely as possible, the actual support conditions of the structure.

The extent of model should be sufficient to establish proper boundary conditions. Where the model has been extended to points well away from the areas of interest within the model, boundary conditions may be reasonably simplified, for example assuming fully fixed conditions for plate elements models.

3.9 Loads

Loads applied on a model are to be as required by the relevant rule or the design loads of the structural member, whichever is greater.

In addition to static loads, other loads such as hull girder and dynamic loads arising out of acceleration, ship motion, etc. are to be considered where applicable and relevant.

In typical cases, it is not necessary to consider the self weight of the structure, unless it is expected to be a significant component of the loads acting on the structure.

Loads are to be applied in a manner so as to match, as closely as possible, the expected distribution and manifestation of the load within the structure in the actual situation.

3.11 Stress Criteria

Unless otherwise specified in these Rules or relevant regulations, individual stress components and, as applicable, direct combinations of such stresses in beam or grillage models are not to exceed the allowable stress \( F \).
\[ F = \frac{F_y}{FS} \]

where

\[ F_y = \text{specified minimum yield strength of the material} \]
\[ FS = \text{Factor of Safety} \]

For static loadings:

\[ = 1.67 \text{ for axial or bending stress} \]
\[ = 2.50 \text{ for shear stress} \]

For loads combining static and dynamic:

\[ = 1.25 \text{ for axial or bending stress} \]
\[ = 1.88 \text{ for shear stress} \]

For plate element models, and unless otherwise specified in these Rules or relevant regulations, the Von-Mises equivalent stress is not to exceed the limits specified in 3-1-4/3.11 TABLE 2 for the specific mesh size.

**TABLE 2**

<table>
<thead>
<tr>
<th>Mesh Size</th>
<th>Stress Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1 \times \text{stiffener spacing (SS)})</td>
<td>(0.90 S_m F_y)</td>
</tr>
<tr>
<td>(\frac{1}{6} \times \text{SS})</td>
<td>(0.95 S_m F_y)</td>
</tr>
<tr>
<td>(\frac{1}{8} \times \text{SS})</td>
<td>(1.00 S_m F_y)</td>
</tr>
<tr>
<td>(\frac{1}{10} \times \text{SS}^{(1)})</td>
<td>(1.06 S_m F_y)</td>
</tr>
<tr>
<td>(\frac{1}{12} \times \text{SS}^{(1)})</td>
<td>(1.12 S_m F_y)</td>
</tr>
</tbody>
</table>

**Notes:**

1. Stress limits greater than \(1.00 S_m F_y\) are to be restricted to small areas in way of structural discontinuities.
2. \(S_m = 1.0 \) for mild steel
   \(= 0.95 \) for HT 32
   \(= 0.908 \) for HT 36
3. For intermediate mesh size, the stress limit may be obtained by linear interpretation
4. For longitudinally effective structure that is modeled without the hull girder loads, the allowable stresses are to be decreased by 10%
PART 3
CHAPTER 2 Hull Structures and Arrangements

CONTENTS

SECTION | 1 Primary Hull Strength
---------|-----------------------|-------|
         | Longitudinal Hull Girder Strength – Monohulls
         | Section Modulus
         | Extension of Midship Section Modulus

Hull Structures and Arrangements

Primary Hull Strength

Longitudinal Hull Girder Strength – Monohulls

The equations are, in general, valid for craft having breadths, \( B \), not greater than twice their depths, \( D \), as defined in 3-1-1. Finite element analysis of the longitudinal hull girder strength is an acceptable alternate analysis to the requirements in 3-2-1/1 through 3-2-1/5. The failure criteria, seaway loads, and finite element method is to be submitted for review.

1.1 Section Modulus

1.1.1 All Craft

The required hull girder section modulus \( SM \) at amidships is to be not less than given by the following equation:

\[
SM = C_1 C_2 L^2 B (C_b + 0.7) K_3 C Q \quad \text{cm}^2 \text{m} (\text{in}^2 \text{ft})
\]

where

\[
C_1 = \begin{cases} 
0.044L + 3.75 & L < 90 \text{ m} \\
10.75 - \left( \frac{300 - L}{100} \right)^{1.5} & 90 \text{ m} \leq L 
\end{cases}
\]

\[
C_1 = \begin{cases} 
0.0134L + 3.75 & L < 295 \text{ ft} \\
10.75 - \left( \frac{984 - L}{328} \right)^{1.5} & 295 \text{ ft} \leq L 
\end{cases}
\]

\[
C_2 = 0.01(0.01, 1.44 \times 10^{-4})
\]

\( L = \) length of craft, in m (ft), as defined in 3-1-1

\( B = \) breadth, in m (ft), as defined in 3-1-1

\( V = \) maximum speed in calm water, in knots, for the loading condition under consideration

\( C_b = \) block coefficient at the design draft, based on the length, \( L \), measured on the design load waterline. \( C_b \) is not to be taken as less than 0.45 for \( L < 35 \text{ m} \) (115 ft) or 0.6 for \( L \geq 61 \text{ m} \) (200 ft). \( C_b \) for lengths between 35 m (115 ft) and 61 m (200 ft) is to be determined by interpolation.

\[
K_3 = \begin{cases} 
0.70 + 0.30 \left( \frac{V/\sqrt{2}}{2.36} \right) & \text{SI/MKS units,} \\
0.70 + 0.30 \left( \frac{V/\sqrt{2}}{2.36} \right) & \text{US Units;}
\end{cases}
\]

\( K_3 \) is not to be taken less than 1, nor more than 1.30.

\( C = \)

1.0 for steel craft

0.90 for aluminum craft
0.80 for fiber-reinforced plastic craft

\[ Q \text{ for steel:} \]
\[ = 1.0 \text{ for ordinary strength steel} \]
\[ = 0.78 \text{ for grade H32 steel} \]
\[ = 0.72 \text{ for grade H36 steel} \]

For other steel grades:
\[ Q_{\text{other}} = \frac{490}{(\sigma_y + 0.66\sigma_u)}\left[\frac{50}{(\sigma_y + 0.66\sigma_u)} + \frac{70900}{(\sigma_y + 0.66\sigma_u)}\right], \text{where } \sigma_y \text{ is not to be greater than } 70\% \sigma_u \]

\[ Q \text{ for aluminum:} \]
\[ = 0.9 + q_5 \text{ but not less than } Q_o \]
\[ q_5 = 115/\sigma_y, (12/\sigma_y, 17000/\sigma_y) \]
\[ Q_o = 635/(\sigma_y + \sigma_u), (65/(\sigma_y + \sigma_u), 92000/(\sigma_y + \sigma_u)) \]
\[ \sigma_y = \text{minimum yield strength of unwelded aluminum in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi}) \text{ (not to be greater than } 0.7\sigma_u) \]
\[ \sigma_u = \text{minimum ultimate strength of welded aluminum in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi}) \]

\[ Q \text{ for fiber reinforced plastic:} \]
\[ = \frac{400}{0.75\sigma_u}, (41/0.75\sigma_u, 58000/0.75\sigma_u) \]
\[ \sigma_u = \text{minimum ultimate tensile or compressive strength, whichever is less, verified by approved test results, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)} \text{. See 2-6-5. Strength properties in the longitudinal direction of the craft are to be used.} \]

1.1.2 Craft 61 m (200 ft) in Length and Over

In addition to meeting the above criteria in 3-2-1/1.1.1, craft of 61 m (20 ft) in length or greater are to comply with the following requirements:

1.1.2(a) Sign Convention of Bending Moment and Shear Force.

The sign convention of bending moment and shear force is as shown in 3-2-1/1.1.2(a) FIGURE 1.
1.1.2(b) Wave Bending Moment Amidships.
The wave bending moment, expressed in kN-m (tf-m, Ltf-ft), may be obtained from the following equations:

\[ M_{ws} = -k_1 C_1 L^2 B (C_b + 0.7) \times 10^{-3} \]  
Sagging Moment

\[ M_{wh} = +k_2 C_1 L^2 B C_b \times 10^{-3} \]  
Hogging Moment

where

\[ k_1 = 110 \text{ (11.22, 1.026)} \]
\[ k_2 = 190 \text{ (19.37, 1.772)} \]

\( C_1, L, B \) and \( C_b \) are as defined in 3-2-1/1.1.1.

1.1.2(c) Still Water Bending Moment.
The maximum still water bending moment in both the hogging and sagging condition is to be submitted. In case the detailed information is not available in the early stages of design, or the still water bending moment is not required to be submitted, the still water bending moment in kN-m (Ltf-ft) can be determined by the following:

\[ M_{sws} = 0 \]  
Sagging Moment

\[ M_{swh} = 0.375 f_p C_1 C_2 L^2 B (C_b + 0.7) \]  
Hogging Moment

where

\[ f_p = 17.5 \text{ kN/cm}^2, \text{ (1.784 tf/cm}^2, 11.33 \text{ Ltf/in}^2) \]

\( C_1, C_2, L, B \) and \( C_b \) are as defined in 3-2-1/1.1.

1.1.2(d) Slamming Induced Bending Moment.
The slamming induced bending moment in kNm (Ltf-ft) can be determined by the following equation:

\[ M_{s\ell} = C_3 \Delta (1 + n_{cg}) (L - \ell_s) \]  
\text{kN - m (tf - m, Ltf - ft)}

where

\[ C_3 = 1.25 \text{ (0.125, 0.125)} \]
\[ \Delta = \text{full load displacement, in metric tons (long tons)} \]
\[ \ell_s = \text{length of slam load, in m (ft)} \]  
\[ = A_R/B_{wl} \]
\[ A_R = 0.697 \Delta / d \text{ m}^2 \text{ (25}\Delta / d \text{ ft}^2) \]
\[ B_{wl} = \text{waterline breadth at the LCG, in m (ft)} \]
\[ n_{cg} = \text{maximum vertical acceleration as defined in 3-2-2/1.1, but (1 + n_{cg}) is not to be taken less than indicated in 3-2-1/1.1.2(d) TABLE 1.} \]

\( L \) is as defined in 3-2-1/1.1.1.
1.1.2(e) Section Modulus.

The required hull-girder section modulus for \(0.4L\) amidships is to be obtained from the following equation:

\[
SM = \frac{M_t C Q}{f_p} \quad \text{cm}^2 - m(\text{in}^2 - \text{ft})
\]

where

\[
M_t = \text{maximum total bending moment. To be taken as the greatest of the following:}
\]

\[
= M_{swh} + M_{wh}
\]

\[
= -M_{sws} - M_{ws}
\]

\[
= M_{sl}
\]

\[
M_{swh} = \text{maximum still-water bending moment in the hogging condition, in kN-m (tf-m, Ltf-ft), as determined in 3-2-1/1.1.2(c).}
\]

\[
M_{sws} = \text{maximum still water bending moment in the sagging condition, in kN-m (tf-m, Ltf-ft), as determined in 3-2-1/1.1.2(c).}
\]

\[
M_{wh} = \text{maximum wave induced bending moment in the hogging condition, in kN-m (tf-m, Ltf-ft), as determined in 3-2-1/1.1.2(b).}
\]

\[
M_{ws} = \text{maximum wave induced bending moment in the hogging condition, in kN-m (tf-m, Ltf-ft), as determined in 3-2-1/1.1.2(b).}
\]

\[
M_{sl} = \text{maximum slamming induced bending moment, in kN-m (tf-m, Ltf-ft), as determined in 3-2-1/1.1.2(d).}
\]

\[
f_p = 17.5 \text{ kN/cm}^2, (1.784 \text{ tf/cm}^2, 11.33 \text{ Ltf/in}^2)
\]

\[C \text{ and } Q \text{ are as defined in 3-2-1/1.1.1.}\]

Consideration may be given to a seakeeping analysis based on craft speed and sea state to determine \(M_{ws}\) and \(M_{wh}\).

1.3 Extension of Midship Section Modulus

Where the still-water bending moment envelope is not submitted or where 3-2-1/1.1.1 governs, the scantlings of all continuous and all effectively developed longitudinal material are to be maintained throughout \(0.4L\) amidships and may be gradually tapered beyond. The area of the strength deck and other effective decks comprising of plating and longitudinal members may be reduced linearly from \(0.4L\) amidships to the ends. The ends of all continuous and effectively developed longitudinal members are to
terminate with back-up brackets extending to and attached to an adjacent transverse member. The bracket is to extend for a distance not less than the depth of the member.

Structure that is not continuous throughout the midships 0.4\(L\) and beyond, but is effectively developed by brackets and welding to provide continuity of area, may be taken to contribute to the hull girder section modulus, provided the buckling strength required by 3-2-4/1.5 is maintained in way of the brackets.

Where the scantlings are based on the envelope curve of still-water bending moments, items included in the hull-girder section modulus amidships are to be extended as necessary to meet the hull-girder section modulus required at the location being considered, taking into account the distance required for the member to become fully effective (See 3-2-1/1.7.2).

The envelope curve of \(M_{ws}\) and \(M_{wh}\) may be obtained by multiplying the midship value by the distribution factor \(M\) in 3-2-1/1.3 FIGURE 2.

![FIGURE 2](image)

**FIGURE 2**

**Distribution Factor** \(M\)

1.5 **Moment of Inertia**

The hull-girder moment of inertia, \(I\), at amidships is to be not less than given by the following equation:

\[
I = \frac{L}{K} SM \text{ cm}^2 - \text{m}^2 (\text{in}^2 - \text{ft}^2)
\]

where

- \(SM\) = required hull-girder section modulus in 3-2-1/1.1.1 or 3-2-1/1.1.2, whichever is greater, in \(\text{cm}^2\cdot\text{m}\) (\(\text{in}^2\cdot\text{ft}\))
- \(K\) = factor dependent on the material and craft length as given in 3-2-1/1.5 TABLE 2 below

\(L\), \(C\) and \(Q\) are as defined in 3-2-1/1.1.1.
TABLE 2  
Factor, $K(2016)$

<table>
<thead>
<tr>
<th>L (m, ft)</th>
<th>Steel</th>
<th>Aluminium</th>
<th>FRP (Basic Laminate)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restricted Service (see 1-2-2/7) $L &lt; 61$ m (200 ft)</td>
<td>50</td>
<td>13.33</td>
<td>1.8</td>
</tr>
<tr>
<td>Unrestricted Service $L \leq 61$ m (200 ft)</td>

</tbody>
</table>

Note: For fiber reinforced plastic laminates that are greater than the ABS basic laminate (as defined in Section 2-6-6) the value for $K$ can be adjusted by the ratio of $E_o/E_b$ where:

$$E_o = \text{the elastic modulus of the actual hull laminate in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)}$$

$$E_b = 6890 \text{ N/mm}^2 \text{ (703 kgf/mm}^2, \text{ 1,000,000 psi)}$$

1.7 Section Modulus and Moment of Inertia Calculation

1.7.1 Items Included in the Calculation

In general, the following items may be included in the calculation of the section modulus and moment of inertia provided they are continuous or effectively developed within midship $0.4L$, have adequate buckling strength, and are gradually tapered beyond the midship $0.4L$.

- Deck plating (strength deck and other effective decks)
- Shell and inner bottom plating
- Deck and bottom girders
- Plating and longitudinal stiffeners of longitudinal bulkheads
- All longitudinals of deck, sides, bottom, and inner bottom. See also 3-2-5/1.1.1

1.7.2 Effective Areas Included in the Calculation

In general, the net sectional areas of longitudinal strength members are to be used in the hull girder section modulus calculations, except that small isolated openings need not be deducted provided the openings and the shadow area breadths of other openings in any one transverse section do not reduce the section modulus by more than 3%. The breadth or depth of such openings is not to be greater than 25% of the breadth or depth of the member in which it is located with a maximum of 75 mm (3 in.) for scallops. The shadow area of an opening is the area forward and aft of the opening enclosed by the lines tangential to the corners of the opening intersecting each other to form an included angle of 30 degrees.

1.7.3 Section Modulus to the Deck or Bottom

The section modulus to the deck or bottom is obtained by dividing the moment of inertia by the distance from the neutral axis to the molded deck at side amidships or baseline, respectively. Where a long deckhouse or superstructure is considered as part of the hull girder, the section modulus to the deck is obtained by dividing the moment of inertia by the distance from the neutral axis to the top of the bulwark, deckhouse or superstructure.

1.7.4 Breaks

Craft having partial superstructures are to be specially strengthened in way of breaks to limit the local increase in stresses at these locations. The main deck plate and side shell plate thickness is to
be increased a minimum of 25%, but the increase need not exceed 6.5 mm (0.25 in.). This increase is to extend well beyond the break in both directions in such a fashion to provide a long gradual taper. Where breaks of the superstructure (e.g., long forecastle) are appreciably beyond the amidships \(0.5L\), these requirements may be modified. Gangways, large freeing ports and other openings in the shell or bulwarks are to be kept well clear of breaks, and any holes which must be unavoidably be cut in the plating are to be kept as small as possible and are to be circular or oval in form.

1.9 Hull Girder Shear Strength Calculation – For Craft 61 m (200 ft) in Length and Over

1.9.1 General
The nominal total shear stresses due to still-water and wave-induced loads are to be based on the maximum algebraic sum of the shear force in still-water, \(F_{sw}\), the wave-indicated shear force, \(F_w\), and the slam induced shear force, \(F_{sl}\), at the location being considered. The thickness of the side shell is to be such that the nominal total shear stress as obtained by 3-2-1/1.9.3 are not greater than \(11.0/Q\) kN/cm\(^2\) (1.122/Q tf/cm\(^2\), 7.122/Q Ltf/in\(^2\)) where \(Q\) is as defined in 3-2-1/1.1.1. Consideration is also to be given to the shear buckling strength of the side shell plating.

1.9.2 Wave Shear Forces
The envelopes of maximum shearing forces induced by waves, \(F_w\), as shown in 3-2-1/Figures 3 and 4 may be obtained from the following equations:

\[
F_{wp} = +kF_1C_1LB(C_b + 0.7) \times 10^{-2} \quad \text{For positive shear force}
\]
\[
F_{wn} = -kF_2C_1LB(C_b + 0.7) \times 10^{-2} \quad \text{For negative shear force}
\]

where

\(F_{wp}, F_{wn}\) = maximum shearing force induced by wave, in kN (tf, Ltf)

\(k = 30 (3.059, 0.2797)\)

\(F_1\) = distribution factor as shown in 3-2-1/1.9.2 FIGURE 3

\(F_2\) = distribution factor as shown in 3-2-1/1.9.2 FIGURE 4

\(C_1, L, B\) and \(C_b\) are as defined in 3-2-1/1.1.1.
1.9.3 Slam Induced Shear Force

The slamming induced shear force can be determined by the following equation:

\[ F_{sl} = C_4 F_1 \Delta (n_{cg} + 1) \quad \text{kN}(\text{tf, Ltf}) \quad \text{For positive shear force} \]

\[ F_{sl} = C_4 F_2 \Delta (n_{cg} + 1) \quad \text{kN}(\text{tf, Ltf}) \quad \text{For negative shear force} \]

where
\( C_4 = 4.9 \ (0.5) \)
\( \Delta = \) full load displacement in metric tons (long tons)
\( n_{cg} = \) maximum vertical acceleration as defined in 3-2-2/1.1

1.9.4 Shear Strength

For craft without continuous longitudinal bulkheads, the nominal total shear stress \( f_s \) in the side shell plating may be obtained from the greater of the following equations:

\[
f_s = (F_{sw} + F_w)m/2t_sI
f_s = F_{sl}m/2t_sI
\]

where

\( f_s = \) nominal total shear stress, in kN/cm \(^2\) (tf/cm \(^2\), Ltf/in \(^2\))
\( I = \) moment of inertia of the hull girder section, in cm\(^4\) (in\(^4\)), at the section under consideration
\( m = \) first moment about the neutral axis, of the area of the effective longitudinal material between the horizontal level at which the shear stress is being determined and the vertical extremity of effective longitudinal material, taken at the section under consideration, in cm\(^3\) (in\(^3\))
\( t_s = \) thickness of the side shell plating, at the position under consideration, in cm (in.)
\( F_{sw} = \) hull-girder shearing force in still-water, in kN (tf, Ltf)
\( F_w = F_{wp} \) or \( F_{wn} \) as specified by 3-2-1/1.9.2, depending upon loading
\( F_{sl} = \) slam induced shear force, in kN (Ltf), as indicated in 3-2-1/1.9.3. The slam induced shear force is to be applied in both the hogging and sagging conditions

1.9.5 Shearing Strength for Craft with Two or Three Longitudinal Bulkheads

For craft having continuous longitudinal bulkheads the total shear stresses in the side shell and longitudinal bulkhead plating are to be calculated by an acceptable method. In determining the still-water shear force, consideration is to be given to the effect of non-uniform athwartship distribution of loads. The methods described in 3-2-A1 of the ABS Rules for Building and Classing Marine Vessels may be used as a guide in calculating the nominal total shear stress \( f_s \) related to the shear flow in the side shell or longitudinal bulkhead plating. Alternative methods of calculation will also be considered. One acceptable method is shown in 5C-2-A1 of the ABS Rules for Building and Classing Marine Vessels.

1.9.6 Hull Girder Shear Strength – FRP Craft

Hull girder shear strength will be specially considered on fiber reinforced plastic craft over 24 m (79 ft) in length.

1.9.7 Craft of Unusual Proportion

Craft having unusual proportions will be specially considered.

1.11 Hull Girder Torsional Loads

Torsional calculations may be required for craft with large deck openings. Racking load calculations may be required for craft with tall superstructures.
3 Primary Hull Strength – Twin-Hulled Craft

3.1 Longitudinal Hull Girder Strength

The following applies to catamarans, surface effect craft, and similar configuration twin hulled craft.

The longitudinal strength requirements for twin-hulled craft are as given in 3-2-1/1.1, with the following modifications:

i) \( B \) is to be taken as the sum of the waterline breadths of each hull.

ii) For craft less than 61 m (200 ft), longitudinal shear strength need not be considered unless they have unusual or highly concentrated loads. For craft over 61 m (200 ft) the shear strength will be specially considered.

iii) Items as listed in 3-2-1/1.7 may be included in the longitudinal strength calculation for the total cross section of the hulls, with the addition of the cross deck bridging structure. Consideration is to be given to the length over which the cross-deck structure becomes fully effective.

3.3 Catamaran Transverse Loadings

The transverse primary hull loadings are determined by the following equations:

\[
M_{tb} = K_1 \Delta B_{cd} (1 + n_{cg}) \quad \text{kN-m (kgf-m, ft-lbs)}
\]

\[
M_{tt} = K_2 \Delta L (1 + n_{cg}) \quad \text{kN-m (kgf-m, ft-lbs)}
\]

\[
Q_t = K_1 \Delta (1 + n_{cg}) \quad \text{kN (kgf, lbs)}
\]

where

\( M_{tb} = \) design transverse bending moment acting upon the cross structure connecting the hulls

\( M_{tt} = \) design torsional moment acting upon the transverse structure connecting the hulls

\( Q_t = \) design vertical shear force acting upon the transverse structure connecting the hulls

\( K_1 = 2.5 \) (0.255, 0.255)

\( K_2 = 1.25 \) (0.1275, 0.1275)

\( \Delta = \) craft displacement in tonnes (kg, lbs)

\( B_{cd} = \) distance between the hull centerlines, in meters (feet)

\( L = \) length of craft, in meters (feet), as defined in 3-1-1/3

\( n_{cg} = \) vertical acceleration at the craft’s center of gravity, see 3-2-2/1.1, but \((1 + n_{cg})\) is not to be taken less than indicated in 3-2-1/1.1.2(d) TABLE 1

3.5 Transverse Strength for Catamarans and Surface Effect Craft

3.5.1 Direct Analysis

The design loads that are to be applied to the structure are the transverse bending moment, \( M_{tb} \), the torsional moment, \( M_{tt} \), and vertical shear force, \( Q_t \), as defined in 3-2-1/3.3 and the longitudinal bending moments as given in 3-2-1/1.2. The requirements for the direct analysis are given in 3-1-3.
3.5.2 Analysis for Simple Structures
Guidance for the analysis of cross deck structures that are symmetrical forward and aft of a transverse axis at amidships can be found in 3-2-A2.

3.5.3 Design Stresses and Deflections
Regardless of the method of analysis used, the design stresses are as follows:

\[
\sigma_a = \text{design transverse bending stress, } 0.66\sigma_y \text{ for aluminum and steel craft and } 0.33\sigma_u \text{ for FRP craft, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)}
\]

\[
\sigma_{ab} = \text{design torsional or combined stress, } 0.75\sigma_y \text{ for aluminum and steel craft and } 0.367\sigma_u \text{ for FRP craft, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)}
\]

\[
\tau_a = \text{design transverse shear stress, } 0.38\sigma_y \text{ for aluminum and steel craft and } 0.40\tau_u \text{ for FRP craft, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)}
\]

\[
\sigma_y = \text{minimum yield strength of the material, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi). For aluminum the yield strength is to be for the unwelded condition and not to be greater than } 0.7\sigma_{uw}
\]

\[
\sigma_u = \text{minimum tensile or compressive strength, whichever is less, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)}
\]

\[
\sigma_{uw} = \text{ultimate tensile strength of material in the welded condition, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)}
\]

\[
\delta_m = \text{maximum deflection for FRP craft, } (\sigma_a/E)L_I, \text{ in m (in.)}
\]

\[
\tau_u = \text{minimum ultimate through thickness shear strength, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)}
\]

\[
L_I = \text{mean span of cross structure, in cm (in.), as indicated in 3-2-A2/3 FIGURE 2}
\]

\[
E = \text{tensile or compressive modulus of the FRP laminate, whichever is lesser, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)}
\]

3.7 Items Included in Transverse Moment of Inertia and Section Modulus Calculation
The following items may be included in the calculation of the transverse section modulus and moment of inertia provided that are continuous or effectively developed over the entire breadth of the cross structure or wet deck, and have adequate buckling strength:

- Deck plating, main deck and bottom plating of wet deck
- Transverse stiffeners on wet deck
- Transverse bulkheads or web frames which span the wet deck, and are effectively developed into the hulls
- Transverse box beams, that are effectively developed into the hulls
- Continuous transom plating and attached horizontal stiffeners

In general, the effective sectional area of the deck for use in calculating the section modulus is to exclude hatchways and other large openings in the deck.

Superstructures and house tops are generally not to be included in the calculation of sectional properties of the cross structure. Craft having unusual configuration such as cross-deck structure out-of-line with the main hull structure will be specially considered.

3.9 Craft with More Than Two Hulls
Transverse and torsional strength of craft with more than two hulls will be specially considered.
3.11 Hull Girder Torsional Loads

Torsional calculations may be required for craft with large deck openings. Racking load calculations may be required for craft with high superstructures.

5 Strength Considerations for Hydrofoil Borne Craft

5.1 Longitudinal Strength

The hull weight curve showing full load, lightship and partial load (if more severe) is to be submitted. The support reactions for each of the hydrofoils are to be shown. The resulting shear and bending moment diagrams, as derived from these curves, are to be submitted for approval.

Hull deflection under the condition of maximum bending moment is not to exceed 1/200 of the distance between the forward and aft foil attachment points.

5.3 Calculation of Loads from Hydrofoil Appendages

The maximum forces transmitted by any hydrofoil to the craft structure is given by the following equations:

\[ F_L = C_U C_L V^2 A_P \]

\[ F_D = C_U V^2 (C_{DF} A_{FF} + C_{DS} A_{FS}) + \text{(Wetted surface drag)} \]

where

\( F_L \) = maximum lift force on craft exerted by hydrofoil, in kgf (lbs). This force is assumed to act perpendicular to the plane of the foil.

\( F_D \) = maximum drag force on craft exerted by hydrofoil plus strut, in kgf (lbs). This force is assumed to act directly aft from the center of the foil.

\( C_U \) = 13.847 (2.835)

\( C_L \) = peak coefficient of lift for the foil selected.

\( C_{DF} \) = peak coefficient of drag for the foil selected.

\( C_{DS} \) = peak coefficient of drag for the strut section selected.

\( V \) = maximum craft speed, in knots.

\( A_P \) = plan view area of foil, in \( \text{m}^2 \) (\( \text{ft}^2 \))

\( A_{FF} \) = frontal area of foil, in \( \text{m}^2 \) (\( \text{ft}^2 \))

\( A_{FS} \) = frontal area of strut, in \( \text{m}^2 \) (\( \text{ft}^2 \))

Total drag of the foil and strut (or similar appendage) is given by the drag term \( F_D \) that includes the frictional drag coefficient, as a function of wetted surface and Reynolds number.

The strength of the foils and struts are to be based on \( F_L \) and \( F_D \) and the resulting bending moments, shear forces, and vertical forces. The strength of the connections of the struts to the hull is to be based on the bending moments, shear forces, and vertical forces applied through the struts. A factor of safety on the yield strength of the material (aluminum use the as-welded condition) is to be not less than 2.0. Calculations of the bending moment, shear forces, and stiffness, are to be carried out and submitted by the designer.
Additionally, calculations supporting the “Fail-Safe” performance of each foil attachment structure are to be submitted.

Watertight integrity of the shell is to be maintained in the event of a collision of the hydrofoil appendages with a solid object in the water. A design safety factor of 2.0 on the yield strength or 3.0 on the ultimate strength of the foil strut bearing is to be used to assess the strength of the foil for the collision condition.

7 Effective Decks
To be considered effective for use in calculating the hull girder section modulus, the thickness of the deck plating is to comply with the requirements of 3-2-3. The deck areas are to be maintained throughout the midship \(0.4L\) and may be gradually reduced to one half their midship value at \(0.15L\) from the ends. Only that portion of deck which is continuous through the transverse structure may be considered effective.

9 Operating Manual
Craft are to be furnished with an ABS approved operating manual providing guidance on:

i) Means of identifying that the Manual is for the subject craft including principle particulars of the vessel.

ii) Loading conditions on which the design of the craft has been based, including cargo loading on decks, loading ramps, and double bottoms.

iii) There should also be evidence of approved loading and stability conditions on board the craft. These should preferably be included in the operating manual. If they are a separate document, they should be referenced in the operating Manual.

iv) Maximum approved speed and associated displacement.

v) Service Limitations, any scope of operations and/or operational limits as applicable such as distance from port of refuge.

vi) Maximum operational speeds for the various sea-states (significant wave heights) in which the craft is intended to operate, exceeding the design significant wave height defined in 3-2-2/1.1.3 TABLE 1 in conjunction with the OE notation (see 1-1-3/5 TABLE B).

vii) Permissible limits of still-water bending moments and shear forces, for craft 61m (200 ft) in length of greater.

viii) Position and application of watertight and weathertight (doors, hatches etc.) closing appliances necessary to meet the Load Line assignment; identification of doors and hatches to be kept closed at sea; information on storm shutters and their use; location of emergency escapes.

ix) From the aspect of the Flag Administration, depending on the Administration to which the craft is flagged, there will also be a need for other items to be included such as safety plan, fire fighting procedures, means of escape, evacuation procedures, operation of life saving appliances, and requirements for safe operation of the vessel.
Monohulls

The bottom and side pressures are to be checked using the displacement ($\Delta$), speed ($V$), draft ($d$), and running trim ($\tau$) in the full load, half load, and light load conditions. If the craft is receiving a freeboard assignment, the parameters used in the full load condition are to coincide with the assigned freeboard. If the craft is not receiving a freeboard assignment, the parameters used in the full load condition are to correspond to the condition of the craft with the maximum operating deadweight. The parameters used in the half load condition are to correspond to the condition of the craft with 50% of the maximum operating deadweight, and the parameters used in the light load condition are to correspond to the condition of the craft with 10% of the maximum operating deadweight plus the maximum speed of the craft.

1.1 Bottom Design Pressure

The bottom design pressure is to be the greater of those, as given in the following equations, for the location under consideration. Bottom structure design pressures are dependent upon the service in which the craft operates. The bottom design pressure applies to hull bottoms below the chines or the upper turn of the bilge.

1.1.1 Bottom Slamming Pressure

\[
p_{bcg} = \frac{N_1 \Delta}{\bar{w} W} [1 + n_{cg}] F_D \quad \text{kN/m}^2 (\text{tf/m}^2, \text{psi})
\]

\[
p_{bxx} = \frac{N_1 \Delta}{\bar{w} W} \left[1 + n_{xx} \right] \left[\frac{70 - \beta_{bx}}{70 - \beta_{cg}}\right] F_D \quad \text{kN/m}^2 (\text{tf/m}^2, \text{psi})
\]

1.1.2 Bottom Slamming for Craft Less Than 61 meters (200 feet)

The design pressure may be:

\[
p_{bxx} = \frac{N_1 \Delta}{\bar{w} W} [1 + n_{cg}] F_D F_v \quad \text{kN/m}^2 (\text{tf/m}^2, \text{psi})
\]

1.1.3 Hydrostatic Pressure

\[
p_d = N_3(0.64H + d) \quad \text{kN/m}^2 (\text{tf/m}^2, \text{psi})
\]

where

\[
p_{bcg} = \quad \text{bottom design pressure at LCG, kN/m}^2 (\text{tf/m}^2, \text{psi})
\]

\[
p_{bxx} = \quad \text{bottom design pressure at any section clear of LCG, kN/m}^2 (\text{tf/m}^2, \text{psi})
\]

\[
p_d = \quad \text{bottom design pressure based on hydrostatic forces, kN/m}^2 (\text{tf/m}^2, \text{psi})
\]
The vertical acceleration of the craft as determined by a model test, theoretical computation, or service experience (see Section 3-1-3). If this information is not readily available during the early stages of design, the following formula utilizing the average 1/100 highest vertical accelerations at LCG can be used:

\[
n_{cg} = N_1 \left[ \frac{12h_{1/3}}{B_w} + 1.0 \right] \left[ 50 - \beta_{cg} \right] \left( \frac{B_w}{\Delta} \right)^2 g's
\]

Note that g’s are the dimensionless ratio of the acceleration at sea level (9.8m/s², 32.2 ft/s²).

The vertical acceleration, \( n_{cg} \), is typically not to be taken greater than the following:

\[
n_{cg} = 1.39 + k_n \frac{V}{\sqrt{F_D}}
\]

For speeds greater than \( 18\sqrt{L} \) (9.94 \( \sqrt{L} \)) the maximum \( n_{cg} \) is 6.0 g (7.0 g for search and rescue type craft). The vertical accelerations are typically not to be taken less than 1.0 g for craft lengths less than 24 m (79 ft) and 2.0 g for craft lengths less than 12 m (39 ft). Intermediate values can be determined by interpolation. The vertical acceleration will need to be specially considered for craft fitted with seat belts or special shock mitigation seats.

\[
k_n = 0.256 (0.463)
\]

\[
n_{xx} = \text{average of the 1/100 highest vertical accelerations, at any section clear of LCG, in g’s. Can be determined by the following equation:}
\]

\[
= n_{cg}K_v
\]

\[
N_1 = 0.1 (0.01, 0.069)
\]

\[
N_2 = 0.0078 (0.0078, 0.0016)
\]

\[
N_3 = 9.8 (1.0, 0.44)
\]

\[
\Delta = \text{displacement at design waterline, in kg (lbs), see 3-2-2/1}
\]

\[
L_w = \text{craft length on the waterline with the craft at the design displacement and in the displacement mode, in m (ft)}
\]

\[
B_w = \text{maximum waterline beam, in m (ft)}
\]

\[
H = \text{wave parameter, } 0.0172L + 3.653 \text{ m (0.0172L + 11.98 ft), generally not to be taken less than the maximum survival wave height for the craft}
\]

\[
h_{1/3} = \text{significant wave height, m (ft), see 3-2-2/1.1.3 TABLE 1}
\]

\[
\tau = \text{running trim at } V, \text{ in degrees, but generally not to be taken less than } 4^\circ \text{ for craft } L < 50 \text{ m (165 ft), nor less than } 3^\circ \text{ for } L > 50 \text{ m (165 ft). Special consideration will be given to designers values predicted from model tests.}
\]

\[
\beta_{cg} = \text{deadrise at LCG, degrees, generally not to be taken less than } 10^\circ \text{ nor more than } 30^\circ.
\]

\[
\beta_{bx} = \text{deadrise at any section clear of LCG, in degrees, not to be taken less than } 10^\circ \text{ nor greater than } 30^\circ, \text{ see 3-2-2/1.1.3 FIGURE 1.}
\]

\[
V = \text{craft design speed in knots, see 3-2-2/1.1.3 TABLE 1}
\]

\[
F_D = \text{design area factor given in 3-2-2/11.3.7 FIGURE 3 for given values of } A_D \text{ and } A_R.
\]

Generally not to be taken less than 0.4. See 3-2-2/1.1.3 TABLE 2 for minimum values of \( F_D \) for craft less than 24 m (79 ft) in length.

\[
F_V = \text{vertical acceleration distribution factor given in 3-2-2/11.3.7 FIGURE 5.}
\]
$K_V = \text{vertical acceleration distribution factor given in 3-2-2/11.3.7 FIGURE 4.}$

$A_D = \text{design area, cm}^2 (\text{in}^2). \text{For plating it is the actual area of the shell plate panel but not to be taken as more than } 2.5s^2. \text{For longitudinals, stiffeners, transverses and girders it is the shell area supported by the longitudinal stiffener, transverse or girder; for transverses and girders the area used need not be taken less than } 0.33\ell^2.$

$A_R = \text{reference area, cm}^2 (\text{in}^2), 6.95\Delta/d \text{ cm}^2 (1.61\Delta/d \text{ in}^2).$

$s = \text{spacing of longitudinals or stiffeners, in cm (in.)}$

$\ell = \text{unsupported span of internals, in cm (in.). See 3-2-4/1.3.1.}$

$d = \text{stationary draft, in m (ft), vertical distance from outer surface of shell measured at centerline to design waterline at middle of design waterline length, but generally not to be taken as less than } 0.04L. \text{See 3-2-2/1.}$

1.3 **Side and Transom Structure, Design Pressure**

The side design pressure, \( p_s \), is to be not less than given by the equations:

1.3.1 **Slamming Pressure**

\[
p_{xxx} = \frac{N_1 A}{\delta W} (1 + n_{xx}) \bigg( \frac{70 - \beta_{xx}}{70 - \beta C_g}\bigg) F_p \quad \text{kN/m}^2 (\text{tf/m}^2, \text{psi})
\]

1.3.2 **Hydrostatic Pressure**

\[
p_s = N_3 (H_s - y) \quad \text{kN/m}^2 (\text{tf/m}^2, \text{psi})
\]

1.3.3 **Fore End**

\[
P_{sf} = 0.28 F_a C_P N_3(0.22 + 0.15 \tan \alpha)(0.4 V \sin \beta + 0.6 \sqrt{L})^2 \quad \text{kN/m}^2 (\text{tf/m}^2)
\]
\[
P_{sf} = 0.92 F_a C_P N_3(0.22 + 0.15 \tan \alpha)(0.4 V \sin \beta + 0.33 \sqrt{L})^2 \quad \text{psi}
\]

where \( L \) is generally not to be taken less than 30 m (98 ft)

where
$p_{sxx} =$ side design slamming pressure at any section clear of LCG, in kN/m\(^2\) (tf/m\(^2\), psi). For craft greater than 24 m (79 ft) in length, the side design slamming pressure applies both along the entire length below \(L/12\) above baseline and to the region forward of 0.125\(L\).

\[ p_s = \text{side design pressure due to hydrostatic forces, in kN/m}^2\ (\text{tf/m}^2, \text{psi}), \text{but is not to be taken less than the following:} \]
\[ = 0.05N_2L \text{ kN/m}^2\ (\text{tf/m}^2, \text{psi}) \text{at or below } L/15 \text{ above the base line or any height above base line forward of 0.125L from the stem} \]
\[ = 0.033N_2L \text{ kN/m}^2\ (\text{tf/m}^2, \text{psi}) \text{above } L/15 \text{ above the base line, aft of 0.125L from the stem} \]

\[ p_{sf} = \text{side design pressure for forward of 0.125L from the stem.} \]
\[ H_s = 0.083L + d \text{ in meters (feet), but it is not to be taken less than } D + 1.22 \text{ in meters (D + 4 in feet) for craft less than 30 m (100 ft)} \]
\[ = 0.64H + d \text{ in meters (feet) for craft over 30 m (100 ft); where } H \text{ is defined in 3-2-2/1.1} \]
\[ y = \text{distance above base line of location being considered, in m (ft)} \]
\[ L = \text{craft length as defined in 3-1-1/3} \]
\[ \beta_{sx} = \text{deadrise of side at any section clear of LCG, in degrees, not to be taken greater than 55°, see 3-2-2/1.1.3 FIGURE 1} \]
\[ C_F = 0.0125L \text{ for } L < 80 \text{ m (0.00381L for } L < 262 \text{ ft)} \]
\[ = 1.0 \text{ for } L \geq 80 \text{ m (262 ft)} \]
\[ F_a = 3.25 \text{ for plating and 1.0 for longitudinals, transverses and girders} \]
\[ \alpha = \text{flare angle, the angle between a vertical line and the tangent to the side shell plating, measured in a vertical plane at 90° to the horizontal tangent to the side shell, see 3-2-2/1.1.3 FIGURE 1} \]
\[ \beta = \text{entry angle, the angle between a longitudinal line, parallel to the centerline and the horizontal tangent to the side shell, see 3-2-2/1.1.3 FIGURE 1} \]

\[ N_1, N_3, \Delta, L_w, B_w, V, n_{xx}, \beta_{cg}, H, d \] and \(F_D\) are as defined in 3-2-2/1.1.

### 3 Multi-Hull and Surface Effect Craft

The bottom and side pressures are to be checked using the displacement (\(\Delta\)), speed (\(V\)), draft (\(d\)) and running trim (\(\tau\)) in the full load, half load and lightship conditions. If the craft is receiving a freeboard assignment, the parameters used in the full load condition are to coincide with the approved freeboard assignment. If the craft is not receiving a freeboard assignment, the parameters used in the full load condition are to correspond to the maximum operating deadweight. The parameters used in the half load condition are to correspond to 50% of the maximum operating deadweight, and the parameters used in the lightship condition are to correspond to 10% of the maximum operating deadweight plus the maximum speed of the craft. The on-cushion speed is to be used for surface effect craft.
3.1 **Bottom Design Pressure**

The bottom design pressure is to be the greater of the following equations, for the location under consideration. Bottom design pressures are dependent upon the service in which the craft operates. The bottom design pressure applies to hull bottoms below the chines or the upper turn of the bilge for catamarans, trimarans or other multihulled craft and surface effect craft. Bottoms of twin hull surface effect craft shall be considered as catamaran hulls for the purpose of calculation of the bottom slamming pressure.

3.1.1 **Bottom Slamming Pressure**

\[
p_{bg} = \left(\frac{N_1 \Delta}{\bar{L} \Bar{W} \Delta \Delta} \right) [1 + n_{cg}] F_D \quad \text{kN/m}^2 (\text{tf/m}^2, \text{psi})
\]

\[
p_{bx} = \left(\frac{N_1 \Delta}{\bar{L} \Bar{W} \Delta \Delta} \right) \left[ 1 + n_{xx} \left( \frac{70 - \beta_{xx}}{70 - \beta_{cg}} \right) \right] F_D \quad \text{kN/m}^2 (\text{tf/m}^2, \text{psi})
\]

3.1.2 **Bottom Slamming for Craft Less Than 61 meters (feet)**

The design pressure may be:

\[
p_{bx} = \left(\frac{N_1 \Delta}{\bar{L} \Bar{W} \Delta \Delta} \right) [1 + n_{cg}] F_D F_V \quad \text{kN/m}^2 (\text{tf/m}^2, \text{psi})
\]

3.1.3 **Hydrostatic Pressure**

\[
p_d = N_3(0.64H + d) \quad \text{kN/m}^2 (\text{tf/m}^2, \text{psi})
\]

where

\[
n_{cg} = \text{the vertical acceleration of the craft as determined by a model test, theoretical computation, or service experience (see Section 3-1-3). If this information is not readily available during the early stages of design, the following formula utilizing the average 1/100 height vertical accelerations at LCG can be used:}
\]

\[
n_{cg} = N_2 \left[ \frac{12h_1}{h_1 + 10} \right] r \left[ 50 - \beta_{cg} \right] \frac{v^2 (N_h B_w)^2}{\Delta} \quad g's
\]

The maximum and minimum vertical accelerations defined in 3-2-2/1.1 are applicable to multihull craft.

\[
B_w = \text{maximum waterline beam of one hull, in m (ft)}
\]

\[
N_h = \text{number of hulls}
\]

\[
p_{bg}, p_{bx}, N_1, N_2, N_3, \Delta, L, W, V, F_v, n_{xx}, \beta_{xx}, \beta_{cg}, H, d \text{ and } F_D \text{ are as defined in 3-2-2/1.1}
\]

3.3 **Side and Transom Structure, Design Pressure**

The side design pressure, \( p_s \), is to be not less than given by the equations:

3.3.1 **Slamming Pressure**

\[
p_{sx} = \left(\frac{N_1 \Delta}{\bar{L} \Bar{W} \Delta \Delta} \right) [1 + n_{xx} \left( \frac{70 - \beta_{xx}}{70 - \beta_{cg}} \right) ] F_D \quad \text{kN/m}^2 (\text{tf/m}^2, \text{psi})
\]

3.3.2 **Hydrostatic Pressure**

\[
p_s = N_3( H_s - y ) \quad \text{kN/m}^2 (\text{tf/m}^2, \text{psi})
\]

3.3.3 **Fore End**

\[
p_{sf} = 0.28 F_c C_F N_3 (0.22 + 0.15 \tan \alpha) (0.4 V \sin \beta + 0.6 \sqrt{L})^2 \quad \text{kN/m}^2 (\text{tf/m}^2)
\]
\[ p_{sf} = 0.28F_aC_F N_3 (0.22 + 0.15\tan\alpha)(0.4V\sin\beta + 0.33\sqrt{D})^2 \text{ psi} \]

where \( L \) is generally not to be taken less than 30 m (98 ft)

where

\[ p_{sxx} = \text{side design slamming pressure at any section clear of LCG, in kN/m}^2 (\text{tf/m}^2, \text{psi}). \]

For craft greater than 24 m (79 ft) in length, the side design slamming pressure applies both along the entire length below \( L/12 \) above baseline and to the region forward of 0.125 \( L \).

\[ p_s = \text{side design pressure due to hydrostatic forces, in kN/m}^2 (\text{tf/m}^2, \text{psi}), \]

but is not to be taken less than the following:

\[ = 0.05N_3 L \text{ kN/m}^2 (\text{tf/m}^2, \text{psi}) \text{ at or below } L/15 \text{ above the base line or at any height above base line forward of 0.125L from the stem.} \]

\[ = 0.33N_3 L \text{ kN/m}^2 (\text{tf/m}^2, \text{psi}) \text{ at or below } L/15 \text{ above the base line, aft of 0.125L from the stem.} \]

\[ p_{sf} = \text{side design pressure for forward of 0.125L from the stem.} \]

\[ y = \text{distance above base line, m (ft), of location being considered.} \]

\[ L = \text{craft length, as defined in 3-1-1/3} \]

\[ F_a = 3.25 \text{ for plating and 1.0 for longitudinals, transverses and girders} \]

\[ C_F = 0.0125L \text{ for } L < 80 \text{ m} (0.00381L \text{ for } L < 262 \text{ ft}) \]

\[ = 1.0 \text{ for } L \geq 80 \text{ m} (262 \text{ ft}) \]

\[ \alpha = \text{flare angle, the angle between a vertical line and the tangent to the side shell plating, measured in a vertical plane at } 90^\circ \text{ to the horizontal tangent to the side shell, see 3-2-2/1.1.3 FIGURE 1.} \]

\[ \beta = \text{entry angle, the angle between a longitudinal line, parallel to the centerline and the horizontal tangent to the side shell, see 3-2-2/1.1.3 FIGURE 1.} \]

\[ N_1, N_3, D, L_{wp}, V, n_{xx}, b_{c,g}, H_a, d \text{ and } F_D \text{ are as defined in 3-2-2/1.1, } \beta_{sx} \text{ is as defined in 3-2-2/1.3.} \]

\[ N_h \text{ and } B_w \text{ are as defined in 3-2-2/3.1.} \]

### 3.5 Wet Deck or Cross Structure

The wet deck design pressure is to be determined by the following equations:

\[ p_{wd} = 30N_1F_DF_1V_1(1 - 0.85h_a/h_1^{1/3}) \text{ kN/m}^2 (\text{tf/m}^2, \text{psi}) \]

where
\[ N_3 = 0.10 (0.010, 0.00442) \]
\[ h_a = \text{vertical distance, in m (ft), from lightest draft waterline to underside of wet deck, at design point in question. } h_a \text{ is not to be greater than } 1.176 \sqrt[3]{h_1} \]
\[ F_I = \text{wet deck pressure distribution factor as given in 3-2-2/11.3.7 FIGURE 6} \]
\[ V_I = \text{relative impact velocity as given below:} \]
\[ = \frac{4h_1}{\sqrt{L}} + 1 \text{ m/s} \]
\[ = \frac{7.24h_1}{\sqrt{L}} + 3.28 \text{ ft/s} \]

\[ V, h_{1/3} \text{ and } F_D \text{ are as defined in 3-2-2/1.1.} \]

5 Deck Design Pressures – All Craft

The design pressures, \( p_d \), are to be as given in 3-2-2/11.3.7 TABLE 3, see 3-2-2/11.3.7 FIGURE 2.

7 Superstructures and Deckhouses – All Craft

The design pressures, \( p_d \), are to be as given in 3-2-2/11.3.7 TABLE 4.

9 Bulkhead Structure, Design Pressure – All Craft

9.1 Tank Boundaries

The design pressure for tank boundaries, for both integral and non-integral tanks is to be not less than the following equations, whichever is greater:

\[ p_t = N_3 h \text{ kN/m}^2 (\text{tf/m}^2, \text{psi}) \]
\[ p_t = \rho g (1 + 0.5n_{xx})h_2 \text{ kN/m}^2 (\text{tf/m}^2, \text{psi}) \]

where

\[ N_3 = \text{as defined in 3-2-2/1.1} \]
\[ h = \text{greatest of the following distances, in m (ft), from lower edge of plate panel or center of area supported by stiffener, to:} \]

1) A point located above the top of the tank, at a distance of two-thirds the height from the top of the tank to the top of the overflow.
2) A point located at two-thirds of the distance to the main weather deck.
3) A point located above the top of the tank, not less than the greater of the following:
   i) \( 0.01L + 0.15 \text{ m (0.01L + 0.5 ft)} \)
   ii) \( 0.46 \text{ m (1.5 ft)} \)

where \( L \) is the craft length as defined in 3-1-1/3.

\[ \rho g = \text{specific weight of the liquid, not to be taken less than } 10.05 \text{ kN/m}^3 (1.025 \text{ tf/m}^3, 0.44 \text{ lb/ft}^2 \text{-ft}) \]
\[ n_{xx} = \text{vertical acceleration at midspan of the tank, as defined in 3-2-2/1.1} \]
\[ h_2 = \text{distance from lower edge of plate panel or center of area supported by stiffener to the top of the tank, in m (ft)} \]
The heights of overflows are to be clearly indicated on the plans submitted for approval.

Pressurized tanks will be subject to special consideration.

9.3 Watertight Boundaries

The design pressure for watertight boundaries is to be not less than given by the following equation:

\[ p_w = N_3 h \text{ kN/m}^2 (\text{tf/m}^2, \text{psi}) \]

where

\[ N_3 = \text{as defined in 3-2-2/1.1} \]

\[ h = \text{distance, in m (ft), from the lower edge of plate panel or the center of area supported by the stiffener to the bulkhead deck at centerline} \]

11 Operational Loads

Loads on the hull structure are dependent on the craft’s mission, payload and operational environment. For classification purposes, the following payloads must be accounted for in addition to the other loads and pressures defined in this Section:

i) Vehicle and human loads (see 3-2-3/1.9 and 3-2-4/1.15)

ii) Take-off, landing, and stowage of helicopters

11.1 Human Loads

Composite deck structures are to withstand a point load equivalent to the weight of a man (90.7 kg, 200 lbf) in the middle of the plate or the midspan stiffener.

11.3 Helicopter Decks

11.3.1 General

Helicopter decks, where provided, are to meet the following structural and safety requirements. See also 4-4-2/23.1.2 for Non-watertight spaces and 4-5-1/7.

Plans showing the arrangement, scantlings and details of the helicopter deck are to be submitted. The arrangement plan is to show the overall size of the helicopter deck and the designated landing area. If the arrangement provides for the securing of a helicopter or helicopters to the deck, the predetermined position(s) selected to accommodate the secured helicopter, in addition to the locations of deck fittings, for securing the helicopter are to be shown. The type of helicopter to be considered is to be specified and calculations for appropriate loading conditions are to be submitted.

11.3.2 Overall Distributed Loading

For a platform type helicopter decks, a minimum distributed loading of 2010 N/m$^2$ (205 kgf/m$^2$, 42 lbf/ft$^2$) is to be taken over the entire helicopter deck. For all other helicopter decks, the minimum overall distributed load is to be as specified in 3-2-2/11.3.7 TABLE 3.

11.3.3 Helicopter Landing and Impact Loading

A load of not less than 75% of the helicopter maximum take-off weight is to be taken on each of two square areas, 0.3 m × 0.3 m (1 ft × 1 ft). Alternatively, the manufacturer’s recommended wheel impact loading will be considered. The deck is to be considered for helicopter landings at any location within the designated landing area. The structural weight of the helicopter deck is to be added to the helicopter impact loading when considering girders, stanchions, truss supports,
etc. Where the upper deck of a superstructure or deckhouse is used as a helicopter deck and the spaces below are normally manned (quarters, bridge, control room, etc.) the impact loading is to be multiplied by a factor of 1.15.

11.3.4 Stowed Helicopter Loading

If provisions are made to accommodate helicopter secured to the deck in a predetermined position, the structure is to be considered for a local loading not to be taken less than:

\[ P_{HC} = W_{to}(1 + 0.5n_{xx}) + C_e \text{ kN/m}^2(\text{tf/m}^2, \text{psi}) \]

where

\[ W_{to} = \text{maximum take-off weight} \]

\[ n_{xx} = \text{same as 3-2-2/1.1} \]

\[ C_e = 0.49 (0.05, 0.07) \]

11.3.5 Special Landing Gear

Helicopters fitted with landing gear other than wheels will be specially considered.

11.3.6 Loading due to Motions of Craft

The structure supporting helicopter decks is to withstand the loads resulting from the motions of the craft.

11.3.7 Environmental Loading

Calculations are to consider anticipated wind and wave impact loadings on helicopter decks and their supporting structures.

FIGURE 6
Wet Deck Pressure Distribution Factor \( F_I \)

Distance Along \( L_w \) from Afterward End of \( L_w \)
1.1 General

The bottom shell is to extend from the keel to the chine or upper turn of bilge. In general the side shell is to be of the same thickness from its lower limit to the gunwale.

All plating is to meet the requirements for thickness as given in 3-2-3/1.3.

In addition those areas of plating associated with primary hull strength are to meet the buckling criteria as given in 3-2-3/1.5. Where plate panels are subjected to other bending, biaxial, or a combination of stresses, they will be specially considered.

The thickness of the shell plating in way of skegs, shaft struts, hawse pipes, etc. is to be increased by 50% over that obtained from 3-2-3/1.3.

The thickness of water jet tunnels and transverse thruster tubes is to be in accordance with 3-2-3/1.7.

Where the plating forms decks for the access, operation or stowage of vehicles, the plating is in addition to meet the requirements of 3-2-3/1.9.

1.3 Thickness

The thickness of the shell, deck or bulkhead plating is to be not less than obtained by the following equations, whichever is greater:

1.3.1 Lateral Loading

$$t = s \sqrt{\frac{pk}{1000 \sigma_a}} \text{ mm}$$

$$t = s \sqrt{\frac{pk}{\sigma_a}} \text{ in.}$$

where

$$s = \text{ spacing, in mm (in.), of the shell, deck, superstructure, deckhouse or bulkhead longitudinals or stiffeners.}$$

$$p = \text{ design pressure, in kN/m}^2 (\text{tf/m}^2, \text{psi}), \text{ given in Section 3-2-2}$$

$$k = \text{ plate panel aspect ratio factor, given in 3-2-3/1.3.1 TABLE 1}$$

$$\sigma_a = \text{ design stress, in N/mm}^2 (\text{kgf/mm}^2, \text{psi}), \text{ given in 3-2-3/1.3.1 TABLE 2}$$

</tbody>
</table>
Notes:

1. \( \sigma_y \) = yield strength of steel or of welded aluminum in N/mm\(^2\) (kgf/mm\(^2\), psi), but not to be taken greater than 70% of the ultimate strength of steel or welded aluminum.

2. The design stress for bottom shell plates under slamming pressure may be taken as \( \sigma_y \) for plates outside the midship 0.4\( L \).

3. The design stress for steel deckhouse plates may be taken as 0.90\( \sigma_y \).

### 1.3.2 Thickness Based on Secondary Stiffening

\[
\begin{align*}
t_s &= 0.01s \text{ mm (in.)} \\
t_{al} &= 0.012s \text{ mm (in.)}
\end{align*}
\]

where

\[
\begin{align*}
t_s &= \text{required thickness for steel craft} \\
t_{al} &= \text{required thickness for aluminum craft}
\end{align*}
\]

\( s \) is as defined in 3-2-3/1.3.1.

### 1.3.3 Minimum Thickness

The thickness of shell plating, decks and bulkheads is to be not less than obtained from the following equations:

#### 1.3.3(a) Bottom Shell

\[
\begin{align*}
t_s &= 0.44\sqrt{Lq_s} + 2.0 \text{ mm} \\
t_s &= 0.009\sqrt{Lq_s} + 0.08 \text{ in.} \\
t_{al} &= 0.70\sqrt{Lq_{sa}} + 1.0 \text{ mm} \\
t_{al} &= 0.015\sqrt{Lq_{sa}} + 0.04 \text{ in.}
\end{align*}
\]

where

\[
\begin{align*}
L &= \text{craft length, as defined in 3-1-1/3} \\
q_s &= 1.0 \text{ for ordinary strength steel; } 245/\sigma_{ys}, (25/\sigma_{ys}, 34000/\sigma_{ys}) \text{ for higher strength steels, but not to be taken less than 0.72} \\
\sigma_{ys} &= \text{yield strength for higher strength steel, in N/mm}^2, \text{ kgf/mm}^2, \text{ psi} \\
q_{sa} &= 115/\sigma_{ya}, (12/\sigma_{ya}, 17000/\sigma_{ya}) \text{ for aluminum alloys} \\
\sigma_{ya} &= \text{minimum unwelded yield strength for aluminum alloys, in N/mm}^2, \text{ kgf/mm}^2, \text{ psi}, \text{ but not to be taken as more than 0.7 of the ultimate tensile strength in the as-welded condition}
\end{align*}
\]

\( t_s \) and \( t_{al} \) as defined in 3-2-3/1.3.2. However, \( t_s \) is not to be taken less than 3.5 mm (0.14 in.) and \( t_{al} \) is not to be taken less than 4.0 mm (0.16 in.)

#### 1.3.3(b) Side Shell

\[
\begin{align*}
t_s &= 0.40\sqrt{Lq_s} + 2.0 \text{ mm}
\end{align*}
\]
where \( t_s \) and \( t_{al} \) are as defined in 3-2-3/1.3.2. However, \( t_s \) is not to be taken less than 3.0 mm (0.12 in.) and \( t_{al} \) is not to be taken less than 3.5 mm (0.14 in.)

\( q_s \), \( q_a \) and \( L \) are as defined in 3-2-3/1.3.3(a).

1.3.3(c) Strength Deck

\[
t_s = 0.40 \sqrt{L q_s} + 1.0 \text{ mm}
\]

\[
t_s = 0.009 \sqrt{L q_s} + 0.04 \text{ in.}
\]

\[
t_{al} = 0.62 \sqrt{L q_a} + 1.0 \text{ mm}
\]

\[
t_{al} = 0.013 \sqrt{L q_a} + 0.04 \text{ in.}
\]

where \( t_s \) and \( t_{al} \) are as defined in 3-2-3/1.3.2. However, \( t_s \) is not to be taken less than 3.0 mm (0.12 in.) and \( t_{al} \) is not to be taken less than 3.5 mm (0.14 in.)

\( q_s \), \( q_a \), and \( L \) are as defined in 3-2-3/1.3.3(a).

1.3.3(d) Lower Decks, W.T. Bulkheads, Deep Tank Bulkheads

\[
t_s = 0.35 \sqrt{L q_s} + 1.0 \text{ mm}
\]

\[
t_s = 0.007 \sqrt{L q_s} + 0.04 \text{ in.}
\]

\[
t_{al} = 0.52 \sqrt{L q_a} + 1.0 \text{ mm}
\]

\[
t_{al} = 0.011 \sqrt{L q_a} + 0.04 \text{ in.}
\]

where \( t_s \), \( t_{al} \), \( q_s \), \( q_a \) and \( L \) are as defined in 3-2-3/1.3.2. However, \( t_s \) is not to be taken less than 3.0 mm (0.12 in.) and \( t_{al} \) is not to be taken less than 3.5 mm (0.14 in.).

Where the use is made of special purpose aluminum extrusions or special welding techniques are utilized the minimum plate thickness, as given in 3-2-3/1.3.3 above, will be specially considered based on location, purpose and material grades.

1.5 Buckling Criteria

1.5.1 Uni-axial Compression

1.5.1(a) Ideal Elastic Stress

\[
\sigma_E = 0.9 m_1 E \left( \frac{t_b}{S} \right)^2 \text{ N/mm}^2 (\text{kgf/mm}^2, \text{psi})
\]

where

\[
m_1 = \text{buckling coefficient as given in 3-2-3/1.5.2(d) TABLE 3.}
\]

\[
E = \text{for steel: } \times 10^5 \text{ N/mm}^2 (21,000 \text{ kgf/mm}^2, 30 \times 10^6 \text{ psi})
\]
for aluminum: \( 6.9 \times 10^4 \text{ N/mm}^2 \) \((7,000 \text{ kgf/mm}^2, 10 \times 10^6 \text{ psi}) \)

\[ t_b = \ \text{ thickness of plating, in mm (in.)} \]

\[ s = \ \text{ shorter side of plate panel, in mm (in.)} \]

\[ \ell = \ \text{ longer side of plate panel, in mm (in.)} \]

**1.5.1(b) Critical Buckling Stress.**

The critical buckling stress in compression, \( \sigma_c \), is determined as follows:

\[ \sigma_c = \sigma_E \quad \text{when } \sigma_E \leq 0.5\sigma_y \]

\[ = \sigma_y \left(1 - \frac{\sigma_y}{\sigma_E}ight) \quad \text{when } \sigma_E > 0.5\sigma_y \]

where

\[ \sigma_y = \ \text{ yield stress of material, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi}) \]

*Note:* Generally the unwelded yield strength may be used, but due account should be made for critical or extensive weld zones.

\[ \sigma_E = \ \text{ ideal elastic buckling stress calculated in 3-2-3/1.5.1} \]

**1.5.1(c) Calculated Compressive Stress.**

The compressive stresses are given in the following formula:

\[ \sigma_a = c_5 \frac{(M_t)y}{I} \quad \text{N/mm}^2\text{(kgf/mm}^2, \text{ psi}) \]

where

\[ \sigma_a = \ \text{ working compressive stress in panel being considered, N/mm}^2 \text{ (kgf/mm}^2, \text{ psi), but generally not less than the following:} \]

\[ \frac{f_p}{CQ} \frac{SM_R}{SM_A} \quad \text{N/mm}^2\text{(kgf/mm}^2, \text{ psi}) \]

\[ c_5 = 10^5 \ (10^5, 322,560) \]

\[ M_t = \ \text{ maximum total bending moment as given in 3-2-1/1.1.2(e), kN-m (tf-m, Ltf-ft)} \]

\[ y = \ \text{ vertical distance, in m (ft), from the neutral axis to the considered location} \]

\[ I = \ \text{ moment of inertia of the hull girder, cm}^4 \text{ (in}^4) \]

\[ f_p = 175 \text{ N/mm}^2 \ (17.84 \text{ kgf/mm}^2, 25,380 \text{ psi}) \]

\[ Q = \ \text{ applicable factor for steel or aluminum as defined in 3-2-1/1.1} \]

\[ SM_R = \ \text{ hull girder section modulus as required in Section 3-2-1, cm}^2\text{-m (in}^2\text{-ft)} \]

\[ SM_A = \ \text{ section modulus of the hull girder at the location being considered, cm}^2\text{-m (in}^2\text{-ft)} \]

**1.5.1(d) Permissible Buckling Stress.**

The design buckling stress, \( \sigma_c \), of plate panels [as calculated in 3-2-3/1.5.1(b)] is to be such that:

\[ \sigma_c \geq \sigma_a \]
1.5.2 Shear for Craft 61 m (200 ft) in Length and Over

1.5.2(a) Ideal Elastic Buckling Stress

\[ \tau_E = 0.9 m_2 E \left( \frac{t_b}{s} \right)^2 \text{ N/mm}^2 (\text{kgf/mm}^2, \text{psi}) \]

where

- \( m_2 \) = buckling coefficient as given in 3-2-3/1.5.2(d) TABLE 3
- \( E \) = for steel: \( 2.06 \times 10^5 \text{ N/mm}^2 (21,000 \text{ kgf/mm}^2, 30 \times 10^6 \text{ psi}) \)
  for aluminum: \( 6.9 \times 10^4 \text{ N/mm}^2 (7,000 \text{ kgf/mm}^2, 10 \times 10^6 \text{ psi}) \)
- \( t_b \) = thickness of plating, in mm (in.)
- \( s \) = shorter side of plate panel, in mm (in.)
- \( \ell \) = longer side of plate panel, in mm (in.)

1.5.2(b) Critical Buckling Stress.
The critical buckling stress in shear, \( \tau_c \), is determined as follows:

\[ \tau_c = \tau_E \text{ when } \tau_E \leq 0.5 \tau_y \]

\[ \tau_c = \tau_y \left( 1 - \frac{\tau_y}{4 \tau_E} \right) \text{ when } \tau_E > 0.5 \tau_y \]

where

- \( \tau_y \) = minimum shear yield stress of material, in N/mm\(^2\) (kgf/mm\(^2\), psi)
  \[ \frac{\sigma_{yw}}{\sqrt{3}} \]
- \( \sigma_{yw} \) = welded yield strength of material, in N/mm\(^2\) (kgf/mm\(^2\), psi).

\[ \tau_E = \text{ ideal elastic buckling stress calculated in 3-2-3/1.5.2(a)} \]

1.5.2(c) Calculated Shear Stress.
The working shear stress, \( \tau_a \), in the side shell or longitudinal bulkhead plating is to be calculated by an acceptable and recognized method.

1.5.2(d) Permissible Buckling Stress.
The design buckling stress, \( \tau_c \), of plate panels [as calculated in 3-2-3/1.5.2(b)] is to be such that:

\[ \tau_c \geq \tau_a \]

### TABLE 3

**Buckling Coefficients \( m_1 \) and \( m_2 \)**

<table>
<thead>
<tr>
<th>A</th>

</thead>
<tbody>
<tr>
<td>1.</td>
<td>Plates with longitudinal framing, ( \ell \geq s )</td>
</tr>
</tbody>
</table>
a. For $\sigma' = \sigma$, $m_1 = 4$

b. For $\sigma' = \sigma/3$, $m_1 = 5.8$

c. For intermediate values $m_1$ may be obtained by interpolation between a and b

2. Plates with transverse framing, $\ell \geq s$

a. For $\sigma' = \sigma$, $m_1 = C_2[1 + (s/\ell)^2]^2$

b. For $\sigma' = \sigma/3$, $m_1 = 1.45C_2[1 + (s/\ell)^2]^2$

c. For intermediate values $m$ may be obtained by interpolation between a and b

Values of $C_2$

- 1.30 where supported by floors or deep members
- 1.21 where stiffeners are T-sections or angle bars
- 1.10 where stiffeners are bulb plates
- 1.05 where stiffeners are flat bars

**B Edge Shear**

$$M_2 = 5.34 + 4(s/\ell)^2$$
1.7 Water Jet Tunnels and Transverse Thruster Tubes

1.7.1 Water Jet Tunnels

The thickness for the water jet tunnel plating is to be not less than required by 3-2-3/1.3, neither is it to be less than the greater of the jet manufacturer’s recommended thickness or that obtained from the following equation:

\[ t = s \sqrt[1000]{ \frac{p_{t}k}{\sigma_{a}} } \text{ mm} \]

\[ t = s \sqrt[1000]{ \frac{p_{t}k}{\sigma_{a}} } \text{ in.} \]

where

\[ p_{t} = \text{maximum positive or negative tunnel design pressure, in kN/m}^{2} (\text{tf/m}^{2}, \text{psi}), \text{as provided by the jet manufacturer.} \]

\[ s, k \text{ and } \sigma_{a} \text{ are as given in 3-2-3/1.3.} \]

1.7.2 Transverse Thruster Tunnels

The thickness of the tunnel plating for the transverse thrusters is to be not less than required by 3-2-3/1.3, nor less than obtained from the following equation:

\[ t = 0.008d\sqrt{Q} + 3.0 \text{ mm} \]

\[ t = 0.008d\sqrt{Q} + 0.12 \text{ in.} \]

where

\[ d = \text{inside diameter of the tunnel in mm (in.), but is taken as not less than 968 mm (38 in.)} \]

\[ Q \text{ is as given in 3-2-1/1.1.} \]

1.9 Decks Provided for the Operation or Stowage of Vehicles

Where provision is to be made for the operation or stowage of vehicles having rubber tires, and after all other requirements are met, the thickness of deck plating is to be not less than obtained from the following equation:

\[ t = \sqrt{\frac{\beta W(1 + 0.5n_{xx})}{\sigma_{a}}} \text{ mm} \text{(in.)} \]

where

\[ W = \text{static wheel load, in N (lbf)} \]

\[ n_{xx} = \text{average vertical acceleration at the location under consideration as defined in 3-2-2/1.1} \]

\[ \beta = \text{as given in 3-2-3/1.9 FIGURE 1} \]

\[ \sigma_{a} = \text{design stress for decks, in N/mm}^{2} (\text{kgf/mm}^{2}, \text{psi}), \text{given in 3-2-3/1.3.1 TABLE 2} \]

For wheel loading, strength deck plating thickness is to be not less than 110% of that required by the above equation, and platform deck plating thickness is to be not less than 90% of that required by the above equation.
Where the wheels are close together, special consideration will be given to the use of combined imprint and load. Where the intended operation is such that only the larger dimension of the wheel imprint is perpendicular to the longer edge of the plate panel, then \( b \) below may be taken as the smaller wheel imprint dimension, in which case, \( a \) is to be the greater one.

**FIGURE 1**

Values for \( \beta \)

**Notes:**

\( s \) = spacing of deck beams or deck longitudinals, in mm (in.)

\( \ell \) = length of plate pane, in mm (in.)

\( a \) = wheel imprint dimension, in mm (in.), paralleled to the shorter edge, \( s \), of the plate panel

\( b \) = wheel imprint dimension, in mm (in.), parallel to the longer edge, \( \ell \), of the plate panel

3 **Aluminum Extruded Planking, Sandwich Panels and Corrugated**

3.1 **Aluminum Extruded Planking**

Extruded planking is to be reviewed similar to a conventional stiffener and plate combination. The required thickness of the planking between stiffeners is given in 3-2-3/1.3 and 3-2-3/1.5. For box and truss type extrusion, the plate spacing is to be taken as the maximum unsupported span of plate as indicated in 3-2-3/3.1 FIGURE 2. The stiffeners on the planking are to comply with the requirements in 3-2-4/1.3, 3-2-4/1.5 and 3-2-4/1.7. The geometry of stiffeners in box and truss type extrusions is as indicated in 3-2-3/3.1 FIGURE 2. The individual planking pieces are to be attached by continuous welding for the main deck and can be welded intermittently for interior accommodation decks. The intermittent weld for the
interior decks is to be sized in accordance with 3-2-13/1 for beams and stiffeners to deck. The use of adhesives for attaching planking members used for weather coverings is to be specially considered.

FIGURE 2
Extruded Planking

![Extruded Planking Diagram]

3.3 Sandwich Panels

A sandwich panel is a panel with thin skins attached to a thicker core material. These panels are to be typically used on enclosed decks or bulkheads. Where exposed panels are proposed the effects due to heat and the coefficients of thermal expansion are to be addressed. In general, the inner and outer skins are to be of the same thickness. The use of aluminum sandwich panels for helicopter decks and wheel loading will be specially considered. Sandwich panels are to comply with the equations given below:

3.3.1 Section Modulus of Skins

The section modulus about the neutral axis of a strip of sandwich panel, 1 cm (1 in.) wide is not to be less than the following equation:

\[
SM = \frac{s^2pk}{6 \times 10^5 \sigma_a} \quad \text{cm}^3
\]

\[
SM = \frac{s^2pk}{60 \times 10^{-6} \sigma_a} \quad \text{in}^3
\]

where

\( s \) = spacing of the shell or deck longitudinals or superstructure, deckhouse or bulkhead stiffener, in mm (in.). It is always to be the lesser dimension of the unsupported plate panels

\( p \) = design pressure, given in Section 3-2-2

\( k \) = coefficient varying with plate panel aspect ratio, given in 3-2-3/1.3.1 TABLE 1

\( \sigma_a \) = design stress, given in 3-2-3/1.3.1 TABLE 2

3.3.2 Moment of Inertia of Skins

The moment of inertia about the neutral axis of a strip of sandwich panel, 1 cm (1 in.) wide is not to be less than the following equation:

\[
l = \frac{s^3pk_1}{120 \times 10^5 \cdot 0.24E} \quad \text{cm}^4
\]
\[ l = \frac{s^3 p k_1}{0.24 E} \text{ in}^4 \]

where

- \( s \) = spacing of the shell or deck longitudinals or superstructure, deckhouse or bulkhead stiffener, in mm (in.). It is always to be the lesser dimension of the unsupported plate panels.
- \( p \) = design pressure, given in Section 3-2-2.
- \( k_1 \) = coefficient varying with plate panel aspect ratio, given in 3-2-3/1.3.1 TABLE 1.
- \( E \) = tensile modulus of aluminum, in N/mm\(^2\) (kgf/mm\(^2\), psi), as defined in 3-2-3/1.5.2.

### 3.3.3 Core Shear Strength

The thickness of core and sandwich is to be not less than given by the following equation:

\[ \frac{d_o + d_c}{\tau} = \frac{v p s}{\tau} \text{ in}. \]

where

- \( d_o \) = overall thickness of sandwich, in mm (in.).
- \( d_c \) = thickness of core, in mm (in.).
- \( v \) = coefficient varying with plate panel aspect ratio, given in 3-2-3/5.7.3 TABLE 6.
- \( s \) = lesser dimension of plate panel, in mm (in.).
- \( p \) = design pressure, in kN/m\(^2\) (tf/m\(^2\), psi), as defined in Section 3-2-2.
- \( \tau \) = design stress, N/mm\(^2\) (kgf/mm\(^2\), psi), as shown in 3-2-3/5.7.3 TABLE 7.

### 3.3.4 Testing

The core material and the attachment of the skins to the core are to be tested in accordance with the requirements in 2-6-5/11.

### 3.3.5 Attachment

Typically, beams and stiffeners are not to be considered as effectively attached. Panels are not to be bolted to unless the possible damage from heat is addressed. The panels are to be bolted to surrounding structure. The use of adhesives will be specially considered.

### 3.5 Corrugated Panels

#### 3.5.1 Plating

The plating of corrugated panels is to be of the thickness required by 3-2-3/1.3 with the following modification. The spacing to be used is the greater of dimensions \( a \) or \( c \) as indicated in 3-2-4/1.7.1 FIGURE 3.

### 5 Fiber Reinforced Plastic

#### 5.1 General

The shell, decks and bulkheads may be either single skin or sandwich construction. Where both are used, a suitable transition is to be obtained between them with a minimum 12:1 taper ratio.
The bottom shell is to extend to the chine or upper bilge turn. A suitable transition is to be obtained between the bottom and side shell plating. The shell thickness in way of the keel is to be 50% greater and in way of shaft struts and skegs is to be 100% greater than the thickness required by 3-2-3/5.5.1 or 3-2-3/5.5.2, as applicable. For this purpose, pressure \( p_b \) as obtained from 3-2-2/1.1 or 3-2-2/3.1 and actual frame spacing at the location of the member are to be used for 3-2-3/5.5.1. Suitable framing reinforcement is to be provided in way of shaft struts. Bow thruster tube thickness is to be equivalent to the surrounding shell thickness.

The shell, deck or bulkhead laminates may be bi-directional (having essentially same strength and elastic properties in the two in-plane principal axes of the shell, deck or bulkhead) or uni-directional (having different strength or elastic properties in the two principal axes of the shell, deck or bulkhead panels). Bonding angles or tapes are to have essentially same strength and elastic properties as the plating laminate being bonded, and are in general to be in accordance with Section 3-2-6.

### 5.3 Fiber Reinforcement

The basic laminate given in Part 2, Chapter 6 or other approved laminate of glass, aramid or carbon fiber in mat, woven roving, cloth, knitted fabric or non-woven uni-directional reinforcing, plies may be used. Equivalent strength and thickness of other than E-glass base laminate is to be assessed in a laminate stack program on the basis of first ply failure. For the shell and deck a sufficient number of plies are to be laid-up with the warp in the 0° (longitudinal) axis. Warp and fill directions are to be aligned parallel to the respective edges of the shell and deck panels as closely as practicable. Depending on the directionality and fiber orientation of these plies, other plies may be required or permitted in the 90° (transverse) axis; reinforcing plies in other axes such as +45° (diagonal) may also be used, when approved.

Where the strength and stiffness in the two principal axes of the panel are different, panel bending in each of the panel principal axes is to be considered. See 3-2-3/5.5.2 and 3-2-3/5.7.2.

### 5.5 Single Skin Laminate

#### 5.5.1 With Essentially Same Properties in 0° and 90° Axes

The thickness of the shell, deck or bulkhead plating is to be not less than given by the following equations:

**5.5.1(a) All Plating**

\[
t = sc \sqrt{\frac{p k}{\sigma_a}} \text{ mm}
\]

\[
t = sc \sqrt{\frac{p k}{\sigma_a}} \text{ in.}
\]

**5.5.1(b) All Plating**

\[
t = sc \sqrt[3]{\frac{p k_1}{100 k_2 F}} \text{ mm}
\]

\[
t = sc \sqrt[3]{\frac{p k_1}{k_2 F}} \text{ in.}
\]

**5.5.1(c) Strength deck and shell**

\[
t = k_3 (c_1 + 0.26L) \sqrt{q_1} \text{ mm}
\]

\[
t = k_3 (c_1 + 0.0031L) \sqrt{q_1} \text{ in.}
\]

\( L \) is generally not to be taken less than 12.2 m (40 ft).

**5.5.1(d) Strength deck and bottom shell**

\[
t = \frac{4}{k_B} \sqrt{0.6 \sigma_{uc} \frac{S_{MR}}{S_{MA}}} \text{ mm(in.)}
\]
where

\[ s = \text{spacing of the shell or deck longitudinals or superstructure, deckhouse or bulkhead stiffeners, in mm (in.). It is always to be the lesser dimension of the unsupported plate panels} \]

\[ c = \text{factor for plate curvature in the direction parallel to}\ s, \text{given by } (1 - A/s), \text{but is not to be taken less than 0.70} \]

\[ A = \text{distance, in mm (in.), measured perpendicular from the chord length,}\ s, \text{to the highest point of the curved plate arc between the panel edges} \]

\[ p = \text{design pressure given in Section 3-2-2} \]

\[ k \text{ or } k_1 = \text{coefficient varying with plate panel aspect ratio, given in 3-2-3/1.3.1 TABLE 1} \]

\[ k_B = 2.5 \quad \text{with longitudinal framing} \]

\[ = 2.5 \quad \text{with transverse framing and panel aspect ratio of 1.0} \]

\[ = 1.0 \quad \text{with transverse framing and panel aspect ratio 2.0 to 4.0} \]

\[ \sigma_{ad} = \text{design stress given in 3-2-3/5.5.1(d) TABLE 4} \]

\[ k_2 = \begin{align*} &\text{for bottom plating: 0.015 for patrol boats and similar service craft, 0.01 for other craft} \\
&\text{for side plating: 0.020 for patrol boats and similar service craft, 0.015 for other craft} \\
&\text{for superstructures and deckhouse fronts: 0.025} \\
&\text{for other plating: 0.010} \end{align*} \]

\[ E_F = \text{flexural modulus of laminate, in N/mm}^2 (\text{kgf/mm}^2, \text{psi}), \text{in the direction parallel to } s \]

\[ q_1 = 170/F (15.5/F, 25,000/F) \]

\[ L = \text{craft length, in m (ft), as defined in 3-1-1/3} \]

\[ c_1 = 5.7 \text{ mm (0.225 in.)} \]

\[ k_3 = 1.2 \quad \text{for bottom shell structure} \]

\[ = 1.0 \quad \text{for side shell and deck structure} \]

\[ E_c = \text{compressive modulus of elasticity in N/mm}^2 (\text{kgf/mm}^2, \text{psi}) \]

\[ F = \text{minimum flexural strength of laminate, in N/mm}^2 (\text{kgf/mm}^2, \text{psi}) \]

\[ \sigma_{uc} = \text{minimum compressive strength of laminate, in N/mm}^2 (\text{kgf/mm}^2, \text{psi}) \]

\[ SM_R = \text{required hull-girder section modulus given in Section 3-2-1} \]

\[ SM_A = \text{proposed hull-girder section modulus of midship section} \]

For single skin laminates:

\[\sigma_u = \text{minimum flexural strength, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)}\]

For sandwich laminates:

\[\sigma_u = \text{for shell or deck outer skin, minimum tensile strength, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)}\]
\[\sigma_u = \text{for shell or deck inner skin, minimum compressive strength, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)}\]
\[\sigma_u = \text{for bulkheads, lesser of tensile or compressive strength, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi)}\]

Note: \(\sigma_u\) is to be verified from the approved test results. See Section 2-6-5.

5.5.2 With Different Properties in 0° and 90° Axes

For laminates with different strength and elastic properties in the 0° and 90° axes where the strength is less or the stiffness greater in the panel direction perpendicular to \(s\), the thickness is to be also not less than given by the following equations:

5.5.2(a)
\[t = sc\sqrt{\frac{p k_s}{10000\sigma_{as}}}, \text{ mm}\]
\[t = sc\sqrt{\frac{p k_s}{\sigma_{as}}}, \text{ in.}\]

5.5.2(b)
\[t = sc\sqrt{\frac{p k}{4\sigma_{as} E_s}}\frac{E_s}{E_s}, \text{ mm}\]
\[t = sc\sqrt{\frac{p k}{4\sigma_{as} E_s}}\frac{E_s}{E_s}, \text{ in.}\]

where

\[k_s, k_{\ell} = \text{coefficient for plate panel aspect ratio, given in 3-2-3/5.5.2(b) TABLE 5}\]
\[\sigma_{as} = \text{design stress, given in 3-2-3/5.5.1(d) TABLE 4, based on strength properties in the direction parallel to } s\]
\[E_s = \text{flexural modulus of laminate, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi), in the direction parallel to } s\]
\[\sigma_{as} = \text{design stress, given in 3-2-3/5.5.1(d) TABLE 4, based on strength properties in the direction perpendicular to } s\]
\[E_{\ell} = \text{flexural modulus of laminate, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi), in the direction perpendicular to } s\]

\(s, c\) and \(p\) are as defined in 3-2-3/5.5.

5.7 Sandwich Laminate

5.7.1 Laminate with Essentially Same Bending Strength and Stiffness in 0° and 90° Axes

In general the outer and inner skins are to be similar in lay-up and in strength and elastic properties. Special consideration will be given where this is not the case. In general, single skin laminate is to be used in way of the keel and in way of hull appendages such as shaft struts, skegs and rudders and in way of deck fittings, bolted connections, and other areas of concentrated local loads.

The section modulus and moment of inertia about the neutral axis of a strip of sandwich panel, 1 cm (1 in.) wide are to be not less than given by the following equations:

5.7.1(a)

$$SM_o = \frac{(sc)^2pk}{6 \times 10^5 \sigma_{ao}} \text{ cm}^3$$

$$SM_o = \frac{(sc)^2pk}{6 \sigma_{ao}} \text{ in}^3$$

5.7.1(b)

$$SM_i = \frac{(sc)^2pk}{6 \times 10^5 \sigma_{ai}} \text{ cm}^3$$

$$SM_i = \frac{(sc)^2pk}{6 \sigma_{ai}} \text{ in}^3$$

5.7.1(c)

$$I = \frac{(sc)^3pk_1}{120 \times 10^5 k_2 E_{tc}} \text{ cm}^4$$

$$I = \frac{(sc)^3pk_1}{12k_2 E_{tc}} \text{ in}^4$$

where
\( SM_o = \) required section modulus, in \( \text{cm}^3 \) (in\(^3\)), to outer skin.

\( SM_i = \) required section modulus, in \( \text{cm}^3 \) (in\(^3\)), to inner skin.

\( I = \) required moment of inertia, in \( \text{cm}^4 \) (in\(^4\))

\( \sigma_{ao} = \) design stress, for outer skin, given in 3-2-3/5.5.1(d) TABLE 4, based on strength of outer skin in direction parallel to \( s \).

\( \sigma_{ai} = \) design stress, for inner skin, given in 3-2-3/5.5.1(d) TABLE 4, based on strength of inner skin in direction parallel to \( s \).

\( E_{tc} = 0.5(E_c + E_t) \)

\( E_c = \) mean of compressive moduli of inner and outer skins, in N/mm\(^2\) (kgf/cm\(^2\), psi)

\( E_t = \) means of tensile moduli of inner and outer skins, in N/mm\(^2\) (kgf/cm\(^2\), psi)

\( s, c, p, k, k_1 \) and \( k_2 \) are as defined in 3-2-3/5.5.

5.7.2 Laminates with Different Bending Strength and Stiffness in 0° and 90° Axes

Where the strength is less or the stiffness greater in the direction perpendicular to \( s \), the section modulus and moment of inertia about the neutral axis of a strip of sandwich, 1 cm (1 in.) wide are also to be not less than given by the following equations:

5.7.2(a) In direction parallel to \( s \)

\[
SM_o = \frac{(sc)^2 pk_s}{6 \times 10^5 \sigma_{aso}} \quad \text{cm}^3
\]

\( SM_o = \frac{(sc)^2 pk_s}{6 \sigma_{aso}} \quad \text{in}^3 \)

5.7.2(b) In direction parallel to \( \ell \)

\[
SM_o = \frac{(sc)^2 pk_s}{6 \times 10^5 \sigma_{aso} \frac{E_{tc}}{E_s}} \quad \text{cm}^3
\]

\( SM_o = \frac{(sc)^2 pk_s}{6 \sigma_{aso} \frac{E_{tc}}{E_s}} \quad \text{in}^3 \)

5.7.2(c) In direction parallel to \( s \)

\[
SM_i = \frac{(sc)^2 pk_s}{6 \times 10^5 \sigma_{asi}} \quad \text{cm}^3
\]

\( SM_i = \frac{(sc)^2 pk_s}{6 \sigma_{asi}} \quad \text{in}^3 \)

5.7.2(d) In direction parallel to \( \ell \)

\[
SM_i = \frac{(sc)^2 pk_s}{6 \times 10^5 \sigma_{adi} \sqrt{\frac{E_{tc}}{E_s}}} \quad \text{cm}^3
\]

\( SM_i = \frac{(sc)^2 pk_s}{6 \sigma_{adi} \sqrt{\frac{E_{tc}}{E_s}}} \quad \text{in}^3 \)

5.7.2(e) In direction parallel to \( s \)

\[
l = \frac{(sc)^2 pk_1}{120 \times 10^5 k_2 E_s} \quad \text{cm}^4
\]
\[ I = \frac{(sc)^2 pk_1}{12k_2 k_3} \text{ in}^4 \]

where

\[ SM_o = \text{required section modulus, in cm}^3 (\text{in}^3), \text{to outer skin.} \]

\[ SM_i = \text{required section modulus, in cm}^3 (\text{in}^3), \text{to inner skin.} \]

\[ k_\ell, k_s = \text{modified coefficient for plate panel aspect ratio, given in 3-2-3/5.5.2(b) TABLE 5.} \]

\[ \sigma_{aso} = \text{design stress, for outer skin, given in 3-2-3/5.5.1(d) TABLE 4, based on strength properties in direction parallel to } s. \]

\[ \sigma_{a\ell o} = \text{design stress, for outer skin, given in 3-2-3/5.5.1(d) TABLE 4, based on strength properties in direction perpendicular to } s. \]

\[ \sigma_{asi} = \text{design stress for inner skin, given in 3-2-3/5.5.1(d) TABLE 4, based on strength properties in direction parallel to } s. \]

\[ \sigma_{a\ell i} = \text{design stress, for inner skin, given in 3-2-3/5.5.1(d) TABLE 4, based on strength properties in direction perpendicular to } s. \]

\[ E_s = 0.5(E_{ts} + E_{cs}) \]

\[ E_\ell = 0.5(E_{\ell t} + E_{\ell c}) \]

\[ E_{ts}, E_{cs} = \text{respectively, mean of tensile moduli of inner and outer skins, and mean of compressive moduli of inner and outer skins, in N/mm}^2 (\text{kgf/cm}^2, \text{psi}) \text{ in direction parallel to } s. \]

\[ E_{\ell t}, E_{\ell c} = \text{respectively, mean of tensile moduli of inner and outer skins, and mean of compressive moduli of inner and outer skins, in N/mm}^2 (\text{kgf/cm}^2, \text{psi}) \text{ in direction parallel to } \ell. \]

\[ s, c, p, k_1, k_2 \text{ and } E_{\ell c} \text{ are as defined in 3-2-3/5.5.} \]

5.7.3 Shear Strength

The thickness of core and sandwich laminate is to be not less than given by the following equation. Special consideration will be given where cores differing from those in Part 2, Chapter 6 are proposed. See also 3-2-3/5.7.5 for minimum thickness of skin.

\[ \frac{d_o + d_c}{2} = \frac{vps}{1000\tau} \text{ mm} \]

\[ \frac{d_o + d_c}{2} = \frac{vps}{\tau} \text{ in.} \]

where

\[ d_o = \text{overall thickness of sandwich, excluding gel coat, in mm (in.)} \]

\[ d_c = \text{thickness of core, in mm (in.)} \]

\[ v = \text{coefficient varying with plate panel aspect ratio, given in 3-2-3/5.7.3 TABLE 6. Where the elastic properties of the skins are different in the principal axes, } v \text{ is to be taken not less than 0.5.} \]

\[ s = \text{lesser dimension of plate panel, in mm (in.)} \]

\[ p = \text{design pressure, in kN/m}^2 (\text{tf/m}^2, \text{psi}), \text{as defined in Section 3-2-2.} \]

\[ \tau = \text{design stress, in N/mm}^2 (\text{kgf/mm}^2, \text{psi}), \text{as shown in 3-2-3/5.7.3 TABLE 7.} \]
Where cores are scored to facilitate fitting, the scores are to be filled with putty or resin.

The density of polyvinyl chloride foam cores in the shell plating is to be not less than given in the following table:

<table>

</tbody>
</table>

* May be taken as 0.55τ_u where sheer elongation exceeds 40%.

τ_u = minimum core shear strength, in N/mm² (kgf/mm², psi)
5.7.4 Skin Stability

The skin buckling stress $\sigma_c$, given by the following equation, is in general to be not less than $2.0 \sigma_{ai}$ and $2.0 \sigma_{ao}$.

$$\sigma_c = 0.6 \sqrt{E_s \cdot E_{cc} \cdot G_{cc}}$$

where

$E_s =$ compressive modulus of skins, in N/mm$^2$ (kgf/mm$^2$, psi), in $0^\circ$ and $90^\circ$ in-plane axis of panel

$E_{cc} =$ compressive modulus of core, in N/mm$^2$ (kgf/mm$^2$, psi), perpendicular to skins

$G_{cc} =$ core shear modulus, in N/mm$^2$ (kgf/mm$^2$, psi), in the direction parallel to load

5.7.5 Minimum Skin Thickness

After all other requirements are met, the skin thicknesses of laminates complying with basic laminate requirements of Part 2, Chapter 6 are in general to be not less than given by the following equations:

$$t_{os} = 0.35k_3(C_1 + 0.26L) \quad \text{mm}$$

$$t_{os} = 0.35k_3(C_1 + 0.0031L) \quad \text{in.}$$

$$t_{is} = 0.25k_3(C_1 + 0.26L) \quad \text{mm}$$

$$t_{is} = 0.25k_3(C_1 + 0.0031L) \quad \text{in.}$$

where

$t_{os} =$ thickness of outer skin, in mm (in.)

$t_{is} =$ thickness of inner skin, in mm (in.)

$k_3 =$ 1.2 Bottom Shell

= 1.0 Side Shell and Deck

$C_1 =$ 5.7 mm (0.225 in.)

$L =$ craft length, in m (ft), as defined in 3-1-1/3, generally not to be taken as less than 12.2 m (40 ft).

5.7.6 Wheel Loading

Special consideration will be given to the required thickness where provision is made for the operation or stowage of vehicles having rubber tires after all other requirements are met.

7 Plating Subject to Specific Payloads

A first principles analysis is to be performed for all plates that are subject to a specific payload. The maximum stresses and deflections in these plates are not to exceed the stresses given in 3-2-3/7 TABLE 8.

</tbody>
</table>

\(t_s = \) required thickness for steel  
\(t_{al} = \) required thickness for aluminum  
\(Q = \) material factor as defined in 3-2-1/1.1
PART 3
CHAPTER 2 Hull Structures and Arrangements
SECTION 4 Internals

1 Aluminum and Steel

1.1 General
Structural arrangements and details are to be in accordance with Section 3-2-5 and Section 3-2-6. Reference is to be made to 1-1-4/5 regarding requirement for direct analysis of primary structure (i.e., transverse webs and girders). The scantlings given in this section are minimum values. Direct analysis may be specifically required by these Rules or may be submitted by designers in support of alternative arrangements and scantlings. ABS may, when requested, carry out direct analysis on behalf of designers.

1.3 Strength and Stiffness
1.3.1 Section Modulus
The ends of members are to be effectively attached to the supporting structure. The section modulus of each longitudinal, stiffener, transverse web, stringer and girder is to be not less than given by the following equation:

\[ SM = \frac{83.3 \times ps \ell^2}{\sigma_a} \text{ cm}^3 \]

\[ SM = \frac{144 \times ps \ell^2}{\sigma_a} \text{ in}^3 \]

where

- \( p \) = design pressure, in kN/m² (tf/ft², psi), given in Section 3-2-2/1 or Section 3-2-2/5
- \( s \) = spacing, in m (ft), of the longitudinal, stiffener, transverse web or girder, etc.
- \( \ell \) = length, in m (ft), of the longitudinal, stiffener, transverse web or girder, between supports; where bracketed end connections are supported by bulkheads, \( \ell \) may be measured onto the bracket, the distance given on 3-1-2/5.1 FIGURE 2, provided both bracket arms are about the same length. Where transverse members span chines or “knuckles,” \( \ell \) is to be measured as shown in 3-2-4/1.3.1 FIGURE 1 and 3-2-4/1.3.1 FIGURE 2.
- \( \sigma_a \) = design stress, in N/mm² (kgf/mm², psi) as given in 3-2-4/1.3.1 TABLE 1

Stiffeners without end attachments are permitted on watertight bulkheads provided the section modulus is increased by 50%, and provided the bulkhead plating and boundary can transmit the shear forces on the stiffeners.

</table>

σ_y = minimum yield strength, unwelded condition, in N/mm² (kgf/mm², psi). For aluminum, minimum yield stress, welded condition, in N/mm², (kgf/mm², psi)

σ_u = ultimate tensile strength, in N/mm² (kgf/mm², psi)

1.3.2 Moment of Inertia

The moment of inertia of each longitudinal, stiffener, transverse web, stringer or girder, including the plating to which it is attached, is to be not less than given by the following equation:

\[ I = \frac{260ps\ell^3}{K_4E} \text{ cm}^4 \]
\[ I = \frac{54ps\ell^3}{K_4E} \text{ in}^4 \]

where

\[ K_4 = 0.0015 \] for shell and deep tank girders, stringers and transverse webs, longitudinals, and stiffeners constructed of steel.
\[ = 0.0011 \] for deck girders, transverses, longitudinals, and stiffeners constructed of steel.
\[ = 0.0021 \] for shell and deep tank stringers and transverse webs, longitudinals, and stiffeners constructed of aluminum.
\[ = 0.0018 \] for deck girders, transverses, longitudinals, and stiffeners constructed of aluminum.

\[ E = 2.06 \times 10^5 \text{ N/mm}^2 (21,000 \text{ kgf/mm}^2, 30 \times 10^6 \text{ psi}) \] for steel
\[ = 6.9 \times 10^4 \text{ N/mm}^2 (7,000 \text{ kgf/mm}^2, 10 \times 10^6 \text{ psi}) \] for aluminum

\( p, s \) and \( \ell \) are as given in 3-2-4/1.3.1.
1.5 Elastic Buckling of Longitudinal Members

The moment of inertia of the deck or shell longitudinal together with attached plating is not to be less than 1.5 to satisfy the following criteria:

1.5.1 Axial Compression

The critical buckling stress $\sigma_E$ of a beam-column (i.e., the longitudinal and the associated effective plating) with respect to axial compression may be obtained from the following equation:

$$\sigma_E = \frac{E I_a}{c_1 A \ell^2} \ N/\text{mm}^2 (\text{kgf}/\text{mm}^2, \text{psi})$$

where

- $E$ = as defined in 3-2-4/1.3.2
- $I_a$ = moment of inertia, cm$^4$ (in$^4$), of longitudinal, including plate flange
- $c_1$ = 1000 (1000, 14.4)
- $A$ = cross-sectional area, in cm$^2$ (in$^2$), of longitudinal, including plate flange
- $\ell$ = span of longitudinal, in m (ft)

1.5.2 Torsional/Flexural Buckling

The critical torsional/flexural buckling stress with respect to axial compression of a longitudinal including its associated plate may be obtained from the following equation:

$$\sigma_E = \frac{\pi^2 E I_w}{10 c_1 I_p \ell^2} \left( m^2 + \frac{K}{m^2} \right) + 0.385 E I_t I_p \ N/\text{mm}^2 (\text{kgf}/\text{mm}^2, \text{psi})$$

where

- $K = c_2 \frac{c_2^4}{\pi^4 E I_w}$
- $m = 1$ for $0 < K \leq 4$
- $2$ for $4 < K \leq 36$
- $3$ for $36 < K \leq 144$
- $4$ for $144 < K \leq 400$
- $E$ = as defined in 3-2-4/1.3.2
- $c_2 = 10^6 (10^6, 20736)$
- $I_t$ = St. Venant’s moment of inertia, in cm$^4$ (in$^4$), of profile (without plate flange)
  - $= c_3 \frac{h w^3}{3}$ for flat bars (slabs)
  - $= c_3 \left[ \frac{1}{3} h w^3 + b f t f^3 \left( 1 - 0.63 \frac{b f}{t f} \right) \right]$ for flanged profiles
- $c_3 = 10^{-4} (10^{-4}, 1.0)$
- $I_p$ = polar moment of inertia, in cm$^4$ (in$^4$), of profile about connection of stiffener to plate
  - $= c_3 \frac{h p^3}{3}$ for flat bars (slabs)
\[ I_w = c_3 \left( \frac{h_w^3 t_w^2 b_f}{3} + h_w^2 b_f t_f \right) \text{ for flanged profiles} \]

\( I_w \) = warping constant, in cm\(^6\) (in\(^6\)), of profile about connection of stiffener to plate

\[ I_w = c_4 \frac{h_w^3 t_w^2}{36} \text{ for flat bars (slabs)} \]

\[ I_w = c_4 \left( \frac{t_f b_f^2 h_w^2}{12} \right) \text{ for “Tee” profiles} \]

\[ I_w = c_4 \frac{b_f^3 t_p^2}{12 (b_f + h_w)} \left[ t_f^2 \left( b_f^2 + 2 b_f h_w + 4 h_w^2 \right) + 3 t_w b_f h_w \right] \text{ for angles and bulb profiles} \]

\[ c_4 = 10^4 \ (10^6, 1.0) \]

\[ h_w = \text{web height, in mm (in.)} \]

\[ t_w = \text{web thickness, in mm (in.)} \]

\[ b_f = \text{flange width, in mm (in.)} \]

\[ t_f = \text{flange thickness, in mm (in.)} \]

\[ \ell = \text{span of member, in m (ft)} \]

\( s \) = spacing of member, in mm (in.)

\( C \) = spring stiffness exerted by supporting plate panel

\[ C = \frac{k_p b_f^3 t_p^3}{3 s \left( 1 + \frac{1.33 k_p h_w^2 t_p}{s t_w^3} \right)} \text{ N(kgf, lbf)} \]

\[ k_p = 1 - \eta_p, \text{ not to be taken less than zero. For flanged profiles } k_p \text{ need not be taken less than } 0.1. \]

\[ t_p = \text{plate thickness, in mm (in.)} \]

\[ \eta_p = \frac{\sigma_a}{\sigma_{Ep}} \]

\( \sigma_a \) = calculated compressive stress. For longitudinals, members see 3-2-4/1.5.4

\( \sigma_{Ep} \) = elastic buckling stress of supporting plate as calculated in 3-2-3/1.5.1(a)

1.5.3 Critical Buckling Stress

The critical buckling stress in compression, \( \sigma_c \), is determined as follows:

\[ \sigma_c = \sigma_E \text{ when } \sigma_E \leq 0.5 \sigma_y \]

\[ \sigma_c = \sigma_y \left( 1 - \frac{\sigma_y}{4 \sigma_E} \right) \text{ when } \sigma_E > 0.5 \sigma_y \]

where
σ_y = yield strength of material, in N/mm² (kgf/mm², psi)

Note: Generally the unwelded yield strength may be used, but due account should be made for critical or extensive weld zones.

σ_E = ideal elastic buckling stress calculated in 3-2-4/1.5.1

1.5.4 Calculated Compressive Stress

σ_a = \( c_5 \frac{M_t}{I} \) N/mm² (kgf/mm², psi)

where

σ_a = working compressive stress in panel being considered, N/mm² (kgf/mm², psi), but generally not less than the following:

= \( \frac{C_1 \cdot SM_R}{Q \cdot SM_A} \) N/mm² (kgf/mm², psi)

\( c_5 = 10^5 \) (10⁵, 322,560)

\( M_t = \) maximum total bending moment as given in 3-2-1/1.1.2(e), kN-m (tf-m, Ltf-ft)

\( y = \) vertical distance, in m (ft), from the neutral axis to the considered location

\( I = \) moment of inertia of the hull girder, cm⁴ (in⁴)

\( C_1 = 175 \) N/mm² (17.84 kgf/mm², 25,380 psi)

\( SM_R = \) hull girder section modulus, as required in Section 3-2-1, cm²-m (in²-ft)

\( SM_A = \) section modulus of the hull girder at the location being considered, cm²-m (in²-ft)

\( Q = \) material factor as given in 3-2-1/1.1

1.5.5 Design Buckling Stress

The design buckling stress, σ_c, is to be such that:

σ_c ≥ βσ_a

where

\( \beta = \begin{cases} 1.10 & \text{for the web plating of members} \\ 1.20 & \text{for overall buckling of members} \end{cases} \)

1.5.6 Web and Flange Buckling

Local buckling is considered satisfactory provided the following proportions are not exceeded.

1.5.6(a) Flat bars

\[ \frac{d_w}{t_w} \leq 0.5 \left( \frac{E}{\sigma_y} \right)^{1/2} C_2 \]
1.5.6(b) Built-up Sections, Angle Bars and Tee Bars
\[ \frac{d_w}{t_w} \leq 1.5 \left( \frac{E}{\sigma_y} \right)^{1/2} C_2 \]

1.5.6(c) Bulb Plates
\[ \frac{d_w}{t_w} \leq 0.85 \left( \frac{E}{\sigma_y} \right)^{1/2} C_2 \]

1.5.6(d) Outstanding Face Bars and Flanges
\[ \frac{d_w}{t_w} \leq 0.5 \left( \frac{E}{\sigma_y} \right)^{1/2} C_2 \]

Where

\[ t_w = \text{total required thickness, in mm (in.)} \]
\[ d_w = \text{depth of the web, in mm (in.)} \]
\[ E = \text{as defined in 3-2-4/1.3.2} \]
\[ \sigma_y = \text{yield strength of material, in N/mm}^2 \text{ (kgf/mm}^2 \text{, psi)} \]

Note: Generally the unwelded yield strength may be used, but due account should be made for critical or extensive weld zones.

\[ C_2 = 1 \text{ where } \sigma_a > 0.80 \sigma_y \]
\[ = 0.80 \sigma_y / \sigma_a \text{ where } \sigma_a < 0.80 \sigma_y, \text{ and } \sigma_a \text{ is to be taken not less than 0.55} \sigma_y \]

For webs and flanges that do not satisfy these limits, a detailed analysis of buckling strength using an acceptable method should be submitted for review. The ABS Guide for Buckling and Ultimate Strength Assessment for Offshore Structures may be used for reference.

1.7 Corrugated Panels

1.7.1 Stiffeners
The section modulus, \( SM \), for corrugated bulkhead is to be not less than obtained by the requirements in 3-2-4/1.3 with \( \ell \) being the distance between supporting members in m (ft), and \( s \) is equal to \( a + b \) where \( a \) and \( b \) are as defined in 3-2-4/1.7.1 FIGURE 3 in m (ft).

\[ SM = t a^2 / 6 + (a d t / 2) \]

The developed section modulus, \( SM \), may be obtained from the following equation, where \( a \), \( t \), and \( d \) are as indicated in 3-2-4/1.7.1 FIGURE 3.
1.7.2 End Connections
The structural arrangements and size of welding at the ends of corrugations are to be designed to develop the required strength of corrugation stiffeners. Joints within 10% of the depth of corrugation from the outer surface of corrugation, \( d_1 \), are to have double continuous welds with fillet size, \( w \), not less than 0.7 times the thickness of the bulkhead plating or penetration welds of equal strength (3-2-4/1.7.2 FIGURE 4).

1.9 Web Thickness
The thickness of the webs of structural members is not to be less than determined by the following equation:

1.9.1 Webs (2015)

\[
t = \frac{d_w \sqrt{\sigma_y}}{C \sigma_d}
\]

where

\[
t = \text{total required thickness, in mm (in.)}
\]
\[
d_w = \text{depth of the web, in mm (in.)}
\]
\[
C = \begin{cases} 
70 & \text{for steel members} \\
50 & \text{for aluminum members}
\end{cases}
\]
\[ \sigma_d = 235 \text{ N/mm}^2 \ (24 \text{ kgf/mm}^2, 34,000 \text{ psi}) \quad \text{for steel members} \]
\[ = 127.6 \text{ N/mm}^2 \ (12.76 \text{ kgf/mm}^2, 18,500 \text{ psi}) \quad \text{for aluminum members} \]

The web thickness is also not to be less than the following:
\[ t = \frac{1000ps}{2d_w^2\tau_a} \text{ mm} \]
\[ t = \frac{144ps\ell}{2d_w^2\tau_a} \text{ in.} \]

where
- \( t \) = total required thickness, in mm (in.)
- \( p \) = design pressure, in kN/m\(^2\) (tf/m\(^2\), psi), as given in Section 3-2-2
- \( s \) = width of shell or deck supported by the member, in m (ft)
- \( \ell \) = length of member, in m (ft)
- \( d_w \) = depth of the web, in mm (in.)
- \( \tau_a \) = design shear stress, in N/mm\(^2\) (kgf/mm\(^2\), psi)
  \[ = 0.5\tau_y \text{ for steel structure and } 0.5\tau_{yw} \text{ for aluminum structure. For bottom primary structure } 0.75\tau_y \text{ or } 0.75\tau_{yw}. \]
- \( \tau_y \) = minimum shear, unwelded condition, in N/mm\(^2\) (kgf/mm\(^2\), psi)
- \( \tau_{yw} \) = minimum shear yield strength welded condition, in N/mm\(^2\) (kgf/mm\(^2\), psi)

1.11 Attachments

1.11.1 Lug Attachments

The lug weld attachment of the longitudinals to the transverse webs are to have total weld throat area not less than the following equations:
\[ a_w = \frac{1000ps\ell}{2\tau_a} \text{ mm}^2 \]
\[ a_w = \frac{144ps\ell}{2\tau_a} \text{ in}^2 \]

where
- \( a_w \) = \( t_w \times \ell_w \)
- \( t_w \) = weld throat, in mm (in.)
- \( \ell_w \) = total length of weld, in mm (in.)
- \( p \) = design pressure, in kN/m\(^2\) (tf/m\(^2\), psi), as given in Section 3-2-2
- \( s \) = width of shell or deck supported by the member, in m (ft)
- \( \ell \) = length of shell or deck supported by the member, in m (ft)
- \( \tau_a \) = design shear stress, in N/mm\(^2\) (kgf/mm\(^2\), psi), as defined in 3-2-4/1.9.1
1.11.2 End Attachments
The welded end attachments of members, including bracket connections, are to develop the required strength of the member being attached, considering the member as fix ended.

1.13 Direct Analysis Methods
Local structure may be designed using advanced analysis techniques such as non-prismatic beam, grillage, and finite element analysis. The requirements for the use of these types of analysis techniques are in Section 3-1-3.

1.15 Decks Exposed to Vehicle Loads
All longitudinals, beams, and girders of decks that are subject to vehicle loads are to be checked under all possible combinations of these loads. The maximum allowable design stress for these members are given in 3-2-4/1.3.1 TABLE 1

1.17 Tripping Brackets and Stiffeners
Tripping brackets are to be fitted on girders and transverses at a spacing of about 3 m (10 ft). Stiffeners are to be fitted as may be required.

3 Fiber Reinforced Plastic

3.1 General
The structural arrangements and details are to be in accordance with Section 3-2-5 and Section 3-2-6. Laminates may be bi-directional or uni-directional. Bonding angles or tapes are to comply with Section 3-2-5. Laminates of webs, crowns and face bars of stiffeners, transverses and girders may be bi-directional, or multi-axial. Uni-axial caps may be used in the crowns and face bars of these members. In general, the tapes bonding the members, and their secondary bonds, are to develop the strength of the member being attached.

3.3 Fiber Reinforcement
The basic laminate given in Part 2, Chapter 6, or other approved laminates of glass, aramid, or carbon fiber, in mat, woven roving, cloth, knitted fabric, or non-woven uni-directional reinforcing plies may be used. The plies are in general to be laid-up parallel to the direction of the internal. The strength of the laminate in a direction perpendicular to the direction of the internal is in general to be less than 25% of the warp strength except for the uni-directional caps of the flange or crown of the internal members. In way of continuous longitudinal members, the required section modulus, shear area and moment of inertia of transverse members are to be maintained by the shell or deck plating and that part of the transverse member that is continuous over the longitudinal member.

Where higher strength or higher modulus plies are used in the flange or crown of the internal, it may be advisable to provide similar higher strength, higher modulus local plies in the shell or deck plating, in the direction parallel to the internal to balance the strength and stiffness of the high strength and high modulus plies in the flange or crown of the internal.

3.5 Strength and Stiffness
3.5.1 Section Modulus
The section modulus of each longitudinal, stiffener, transverse web and girder including the plating to which it is attached is to be not less than given by the following equation:

\[
SM = \frac{83.3 \times ps \ell^2}{\sigma_a} \text{ cm}^3
\]

\[
SM = \frac{144 \times ps \ell^2}{\sigma_a} \text{ in}^3
\]
where $p$, $s$, $\ell$ and $\sigma_a$ are defined in 3-2-4/1.3.

Where the shell, deck or bulkhead plating, and the webs and flange and crown of the member are of different strength or elastic property plies, consideration is to be given to the effect of the different moduli plies in calculating the moment of inertia and section modulus; the required section modulus is to be considered for each different strength laminate of the member.

### 3.5.2 Moment of Inertia

The moment of inertia of each longitudinal, stiffener, transverse web, stringer or girder, including the plating to which it is attached, is to be not less than given by the following equation:

$$I = \frac{260ps\ell^3}{K_4E} \text{ cm}^4$$

$$I = \frac{54ps\ell^3}{K_4E} \text{ in}^4$$

where

- $K_4 = 0.005$ for shell and deep tank girders, stringers and transverse webs.
- $K_4 = 0.004$ for deck girders and transverses.
- $K_4 = 0.010$ for all other members.
- $E =$ tensile or compressive modulus, in N/mm$^2$ (kgf/mm$^2$, psi) representative of the basic value used in the moment of inertia calculation.

$p$, $s$ and $\ell$ are as given in 3-2-4/1.3.

### 3.5.3 Shear Area

The web area, $A$, of the member is to be not less than given by the following equation:

$$A = \frac{1000ps\ell}{2\tau} \text{ mm}^2$$

$$A = \frac{144ps\ell}{2\tau} \text{ in}^2$$

where

- $A =$ net web area, in mm$^2$ (in$^2$), at location being considered
- $\tau =$ design shear stress, in N/mm$^2$ (kgf/mm$^2$, psi), to be taken not greater than $0.4\tau_u$
- $\tau_u =$ lesser of ultimate shear strength, in N/mm$^2$ (kgf/mm$^2$, psi), in either warp or fill of the web laminate

$p$, $s$ and $\ell$ are as given in 3-2-4/1.3.

Consideration will be given to determining the web area using more detailed methods of determining the shear stress in the web at the neutral axis of the member.

### 3.7 Proportions

The thickness of webs and flanges are to be in accordance with Section 3-2-6.
3.9 Buckling

3.9.1 Single Skin Laminate
Where single skin laminate members are subject to in-plane compressive loading likely to cause axial overall or local buckling, design calculations are to be submitted to show the margin against buckling failure.

3.9.2 Sandwich Laminates
Where sandwich laminate members are subject to in-plane compressive loading, likely to cause axial overall or local buckling of the sandwich, or of the sandwich skins, design calculations are to be submitted to show the margin against buckling failure.

3.11 Tripping Brackets and Stiffeners
Tripping brackets are to be fitted on girders and transverses at a spacing of about 3 m (10 ft). Stiffeners are to be fitted as may be required.

5 Stanchions

5.1 General
The structure under stanchions is to be of sufficient strength to distribute the loads effectively. Stanchions above are to be arranged directly over stanchions below wherever possible; where this is not possible, effective means are to be provided for transmitting the loads to the structure below. Stanchions in double bottoms and under the tops of deep tanks are to be metal and solid in cross section. Stanchions are in general not to be used in the bottom or double bottom structures where subject to high impact loads in service.

5.3 Stanchion Analysis
The load, $W$, on a given stanchion is to be developed from the end reaction from the girders that the stanchion supports. These end reactions are to be developed considering the design pressure for the deck in which they are located plus any point loads from stanchions located on the girder. When cascading the stanchion loads through the structure, the analysis is to consider the load from the deck directly above the stanchion plus the loads from all complete decks and one-half the load from all partial or deckhouse decks. The requirement in 3-2-4/5.5 is given for a simple stanchion that will only need to support the deck directly above. In general, stanchions are to have sectional area not less than $1.015W \text{ cm}^2$ ($0.16W \text{ in}^2$) where the stanchions are subject to tension loads.

5.5 Stanchion Load
The load on a stanchion is to be obtained from the following equation:

$$W = pbs \text{ kN (tf)}$$

$$W = 0.064 pbs \text{ Ltf}$$

where

- $W = \text{load, in kN (tf, Ltf)}$
- $b = \text{mean breadth, in m (ft), of area supported}$
- $s = \text{mean length, in m (ft), of area supported}$
- $p = \text{design pressure, in kN/m}^2 \text{ (tf/m}^2 \text{, psi), given in Section 3-2-2}$
5.7  Permissible Load

The load a stanchion may carry is to be equal to or greater than the load on the stanchion obtained in 3-2-4/5.3. This permissible load is to be obtained from the following equations:

5.7.1  Ordinary Strength Steel Stanchions

\[ W_a = (12.09 - 4.44 \ell / r)A \quad \text{kN} \]

\[ W_a = (1.232 - 0.452 \ell / r)A \quad \text{tf} \]

\[ W_a = (7.83 - 0.345 \ell / r)A \quad \text{Lf} \]

Refer to 3-2-8/3.1 of the Rules for Building and Classing Marine Vessels for high strength steel.

5.7.2  Aluminum-Alloy Stanchions

\[ W_a = (10.00 - 5.82 \ell / r)A \sigma_y / 165 \quad \text{kN} \]

\[ W_a = (1.02 - 0.593 \ell / r)A \sigma_y / 17 \quad \text{tf} \]

\[ W_a = (6.49 - 0.452 \ell / r)A \sigma_y / 24000 \quad \text{Lf} \]

where

\[ W_a = \text{permissible load, in kN (tf, Lf)} \]

\[ r = \text{least radius of gyration of stanchion, in cm (in.)} \]

\[ A = \text{area of stanchion, in cm}^2 \text{ (in}^2) \]

\[ \ell = \text{unsupported length of stanchion, in m (ft)} \]

\[ \sigma_y = \text{minimum yield strength of welded aluminum under consideration, in N/mm}^2 \text{ (kgf/m}^2, \text{ psi)} \]

The adoption of aluminum test values higher than given in Part 2, Chapter 5 will be subject to special consideration.

5.9  FRP Stanchions

FRP stanchions will be subject to special consideration.

5.11  Support by Bulkheads

Bulkheads supporting girders or bulkheads fitted in lieu of stanchions are to be stiffened to provide support not less effective than required for stanchions.

7  Internals Subject to Specific Payloads

A first principles analysis is to be performed for all internals that are subject to a specific payloads. The maximum stresses and deflections in these plates are not to exceed the stresses given in 3-2-4/7 TABLE 2.

**Notes:**

1. Composites will be specially considered for use in this location.
2. For members subjected to axial compression, the factor of safety is to be based on the yield stress or critical buckling stress, whichever is less.
PART 3
CHAPTER 2 Hull Structures and Arrangements
SECTION 5 Hull Structural Arrangement

1 Structural Arrangement – All Materials

1.1 Framing, Webs, Girders, and Non-tight Structural Bulkheads

1.1.1 General

The shell, main deck, and the sides and tops of long superstructures are in general to be longitudinally framed; depending on craft length, speed and structural stability, craft may also be transversely framed. On transversely framed craft, it is to be clearly indicated that the structure has a continuous load path that eliminates hard spots on unsupported structure.

Bulkheads, partial bulkheads or web frames are to be arranged in the main hull and in long superstructures or deckhouses to provide effective transverse rigidity. Bulkheads or deep web frames are to be provided in the main hull under the ends of superstructures or deckhouses.

Longitudinal frames are to be supported by transverse web frames, transverse bulkheads or other transverse structure. For craft over 61 m (200 ft) in length, or on craft where the longitudinal stiffeners need to be included in the offered longitudinal strength calculation to meet the requirements in 3-2-1/1, the longitudinals are to be continuous in way of transverse supporting members, including transverse bulkheads. All other craft may have longitudinal members intercostal to the transverse bulkheads provided that continuity of strength and end fixity are maintained in accordance with 3-1-2/5.9 and 3-2-5/1.1.2. Craft that are under 30.5 m (100 ft) in length, and where the longitudinal stiffeners do not need to be included in the offered longitudinal strength calculation to meet the requirements in 3-2-1/1, may have longitudinal stiffeners that are intercostal to the transverse supporting members and bulkheads providing that continuity of strength and end fixity are maintained in accordance with 3-1-2/5.9 and 3-2-5/1.1.2. With transverse framing, deck and bottom girders are to be provided. Girders may be intercostal at transverse bulkheads provided continuity of strength is maintained and end fixity is provided in accordance with 3-1-2/5.9 and 3-2-5/1.1.2.

Transverses are to be arranged as continuous web rings and girders are to be aligned with stiffeners at bulkheads. Alternative arrangements that provide fixity at the ends of transverses and girders will be specially considered.

1.1.2 Attachments and Stiffening

At supporting members, the attachment of all internal structural members is to provide end fixity and effective load transmission. Special consideration will be given to reduced end fixity where the alternative structure has equivalent strength.

The webs of all members are to be effectively attached to the shell, deck or bulkhead plating, to their supporting members and to face bars in accordance with the requirements in Section 3-2-13.

1.1.3 Engines, Machinery, and other Foundations

The foundations of engines and associated machinery are to be installed to the manufacturer’s recommendations. These foundations are to be constructed to withstand the loads imparted by the equipment they support under the worst intended operating conditions. The rigidity of foundations
and supporting structure shall be sufficient to prevent misalignment, deflection, or vibration, which would interfere with the operation of the equipment.

Foundations supporting waterjets will be specially considered.

Where main engine girders are part of the longitudinal strength of the craft, there is to be continuity of strength and transition to smaller longitudinal structure. The flanges of engine girders are to be tripped at each transverse frame. All changes of engine girder web depth are to be gradual. The angle of this transition is not to exceed 45°.

Foundations of auxiliary equipment are to be similar to that of engine foundations. They are to provide for secure attachment of the equipment and are to be effectively attached to the hull structure.

Crane and davit foundations are to be capable of withstanding the axial load and the maximum overturning moments specified by the crane manufacturer.

The foundations for anchor winches or windlasses are to be designed in accordance with the requirements in 3-5-1/11.3.

Structural members of all foundations are not to be punched or drilled for the attachment of equipment or fittings. Brackets, margin plates, special framing, or weld studs are to be attached to the structure and the components mounted on them and not directly on the structure.

All connections that are constructed with the use of a bi-metallic connection are to be in accordance with 3-2-6/1.1.6 and 3-2-13/3.

Consideration is to be given to the submittal of plans of the foundations for main propulsion units, reduction gears and thrust bearings and of the structure supporting those foundations to the machinery manufacturer for review.

1.3 Watertight Bulkheads

1.3.1 General

All vessels having lengths, \( L \), equal to or exceeding 15 m (50 ft) are to be provided with watertight bulkheads in accordance with this section. The plans submitted are to clearly show the location and extent of each watertight bulkhead. Watertight bulkheads constructed in accordance with the Rules will be recorded in the Record as \( WT \) (watertight), the symbols being prefixed in each case by the number of such bulkheads.

1.3.2 Openings and Penetrations

The number of openings in watertight subdivisions is to be kept to a minimum, compatible with the design and proper working of the vessel. Where penetrations of watertight bulkheads and internal deck are necessary for access, piping, ventilation, electrical cables, etc., arrangements are to be made to maintain the watertight integrity. Relaxation in the watertightness of openings above the freeboard deck may be considered, provided it is demonstrated that any progressive flooding can be easily controlled and that the safety of the vessel is not impaired.

Ventilation penetrations through watertight subdivision bulkheads are to be avoided. Where penetrations are unavoidable, the ventilation ducting is to satisfy watertight bulkhead requirements or watertight closing appliances are to be installed at the bulkhead penetrations. For ventilation penetrations below the bulkhead deck or below damage equilibrium waterlines, the closing appliances are to be operable from the bridge. Otherwise, local, manual controls may be provided.
1.3.3 Collision Bulkhead (2019)

Craft having a length, as defined in Section 3-1-1, of or exceeding 15 m (50 ft) are to be provided with a collision bulkhead fitted not less than $0.05L_f$ or 10 m (32.8 ft), whichever is less, abaft the reference point. At no point on vessels having 500 or more gross tonnage, except as specially permitted, is it to be further than $0.08L_f$ or $0.05L_f + 3$ m (9.84 ft), whichever is greater, from the reference point. The bulkheads are to be intact except for approved pipe penetrations, and are to extend to the main weather deck preferably in one plane. In craft having long superstructures at the forward end, the bulkheads are to be extended weathertight to the superstructure deck. Provided the extensions are not less than $0.05L_f$ abaft the reference point, they need not be fitted directly over the collision bulkhead. In such cases, the part of the deck forming the step is to be weathertight.

On vessels with bow-doors, that part of their sloping loading ramps that form part of the extension of a collision bulkhead and are more than 2.3 m (7.5 ft) above the freeboard deck may extend forward of the limit below.

Collision bulkhead requirements for passenger vessels are as indicated in Part 5C, Chapter 7 of the Marine Vessel Rules.

1.3.4 Reference Point

The reference point in determining the location of the collision bulkhead is the forward end of $L_f$ except that in the case of vessels having any part of the underwater body, such as the bulbous bow, extending forward of the forward end of $L_f$, the required distances are to be measured from a reference point located a distance forward of the forward end of $L_f$. This distance, $x$, is the lesser of the following (see 3-2-5/1.3.4 FIGURE 1):

i) Half the distance between the forward end of $L_f$ and the extreme forward end of the extension, $p/2$ or

ii) $0.015L_f$

iii) 3 m (9.84 ft)

where $L_f$ is as defined in 3-1-1/3.3.

The forward end of $L_f$ is to coincide with the fore side of the stem on the waterline at which $L_f$ is measured.
1.3.5 Engine Room
The engine room is to be enclosed by watertight bulkheads extending to the main weather deck.

1.3.6 Chain Locker
For craft with length \( L \) (as defined in 3-1-1/3) greater than 24 meters (79 feet), chain lockers and chain pipes are to be made watertight up to the weather deck. The arrangements are to be such that accidental flooding of the chain locker cannot result in damage to auxiliaries or equipment necessary for the proper operation of the craft nor in successive flooding into other spaces. Bulkheads between separate chain lockers not forming a part of subdivision bulkhead (see 3-2-5/1.3.6 FIGURE 1A below), or bulkheads which form a common boundary of chain lockers (see 3-2-5/1.3.6 FIGURE 1B below), need not be watertight.

Where means of access into chain lockers are provided, they are to be closed by a substantial cover secured by closely spaced bolts. Doors are not permitted.

Where a means of access to chain lockers is located below the weather deck, the access cover and its securing arrangements are to be in accordance with recognized standards (such as ISO 5894-1999) or equivalent for watertight manholes covers. Butterfly nuts and/or hinged bolts are prohibited as the securing mechanism for the access cover.

For closure of chain pipes, see 3-2-9/23.7.

The arrangements on craft that are not subject to the International Convention on Load Lines or its Protocol may be specially considered.
1.5 Tanks

The arrangements of all integral or independent tank structures, their intended service, and the heights of the overflow pipes are to be indicated clearly on the drawings submitted for approval. As a minimum, all gravity fill integral or independent tank structures shall meet the design criteria for plating and internals in Section 3-2-3 and Section 3-2-4 considering the maximum head pressure imposed on the peripheries.

Where potable water tanks are fitted, water closets are not to be installed on top of the tanks nor are soil lines to run over the tops of the tanks. Pipes containing non-potable liquids are not to be run through the tanks. Attention is directed to the regulations of national authorities that might govern the location, construction or design of such tanks.

Baffle or swash plates are to be provided. Special consideration may be given for the omission of baffle or swash plates providing the effects of fluid slamming on the plate are considered.

Scantlings of pressurized tanks will be subject to special consideration.

All tanks and void spaces are to be accessible for inspection and repair.

1.7 Decks

Where a deck is stepped or has a break, suitable scarphing or brackets are to be provided at the side shell.

Decks passing into superstructures within the $0.5L$ amidships are to be increased in way of the break. See 3-2-1/1.7.4.

1.9 Means of Escape

All main hull spaces are to have two means of escape to the main weather deck. These escapes are to be located as far apart as practicable and are to be operable from both sides. All escape routes are to be readily accessible and unobstructed.

1.11 Double Bottoms

1.11.1 General

Inner bottoms are to be fitted fore and aft between the peaks or as near thereto as practicable in vessels of ordinary design of 500 GT or over. Where, for special reasons, it may be desired to omit the inner bottom, the arrangements are to be clearly indicated on the plans when first submitted for approval. A double bottom need not be fitted in way of deep tanks, provided the safety of the vessel in the event of bottom damage is not thereby impaired. It is recommended that the inner bottom be arranged to protect the bilges as much as possible and that it be extended to the sides of the vessel.

Shell longitudinals and frames in way of deep tanks are to have not less strength than is required for stiffeners on deep tank bulkheads.
1.11.2 Passenger Craft
For passenger craft that are on international voyages that operate more than four hours at operational speed from a port of refuge are to be fitted with double bottoms in accordance with Part 5C, Chapter 7 of the *Marine Vessel Rules*.

1.11.3 Cargo Craft
Cargo craft that are on international voyages that are more than eight hours at operational speed from a port of refuge are to be fitted with double bottoms. The inner bottoms are to be fitted fore and aft between the peaks or as near thereto as practicable. Where, for special reasons in design, it may be desired to omit the double bottom, the arrangement are to be clearly indicated on the plans when first submitted for approval. A double bottom need not be fitted in way of deep tanks provided the safety of the ship in the event of bottom damage is not thereby impaired. It is recommended that the inner bottom be arranged to protect the bilges as much as possible and that it be extended to the sides of the craft. The scantlings of the double bottom are to be fitted in accordance with Sections 3-2-2, 3-2-3, and 3-2-4.

1.13 Doors, Hatches, Scuttles, and Manhole Covers
All doors, hatches, scuttles, and manhole covers, together with their frames and coamings, are to be in accordance with the same requirements as the structure in which they are installed.

1.15 Helicopter Decks
1.15.1 General
Helicopter landing facilities, where provided, are to meet the following structural and safety requirements. The attention of owners, builders and designers is directed to various international and governmental regulations and guides regarding the operational and other design requirements for helicopter landing on craft. See also 4-6-4/3.9.2, and 4-6-7/9 of the *Marine Vessel Rules*.

Plans showing the arrangement of the helicopter deck are to be submitted. The arrangement plan is to show the overall size of the helicopter deck and the designated landing area. If the arrangement provides for the securing of a helicopter or helicopters to the deck, the predetermined position(s) selected to accommodate the secured helicopter, in addition to the locations of deck fittings for securing the helicopter, are to be shown. The type of helicopter to be considered is to be specified and calculations for appropriate loading conditions are to be submitted.

1.15.2 Safety Net
The unprotected perimeter of the helicopter landing deck is to be provided with safety netting or equivalent.

1.15.3 Material
In general, the construction of helicopter decks is to be of steel or other material with equivalent ability to retain structural capacity in a fire. If the helicopter deck forms the deckhead of a deckhouse or superstructure, it is to be insulated to A-60 class standard.

Aluminum alloys may be used for helicopter decks integral if they form part of an aluminum deckhouse or superstructure. They may also be of aluminum alloy, fitted above a steel deckhouse or deck structure, provided the following conditions are complied with:

- *i)* There are to be no openings in the exterior bulkheads directly below the helicopter deck.
- *ii)* All windows in the lower exterior bulkheads are to be fitted with steel shutters.

1.15.4 Means of Escape and Access
The helicopter deck is to be provided with both a main and an emergency means of escape and access for fire fighting and rescue personnel. These means are to be located as far apart from each other as is practicable and preferably on opposite sides of the helicopter deck.
1.17 Compensation

Compensation is to be provided for openings in the shell plating where required to maintain the longitudinal and transverse strength of the hull. All openings are to have well-founded corners. Those in the upper side shell are to be located a suitable distance below the deck edge. Cargo and gangway openings are to be kept well clear of other discontinuities in the hull girder. Local provision is to be made to maintain the longitudinal and transverse strength of the hull.

Thick plating and doublers of sufficient breadth to prevent damage from the flukes of stockless anchors are to be fitted around the hawse pipes.

3 Structural Arrangements – Additional Requirements for Steel and Aluminum Alloys

3.1 Shell Plating

The bottom shell plating is to extend to the chine or upper turn of bilge. In general, the side shell is to be of the same thickness from its lower limit to the gunwale. Increases in thickness and additional stiffening are required in way of skegs, shaft struts, hawse pipes etc. Where a bow thruster tube is fitted to be in accordance with the requirements in 3-2-3/1.7.

5 Structural Arrangements – Additional Requirements for Fiber Reinforced Plastic Hulls

5.1 Tanks

In fiber reinforced plastic construction, non-integral tanks are to be used whenever possible. When integral tanks are used they are to be of single skin construction; the only exception is the tank top plating can be of sandwich construction. No stiffeners within integral tanks are to penetrate the tank boundaries. No gasoline tanks, or tanks containing petroleum products with flash points less than 60°C (150°F) are to be fitted integrally. The design and arrangements of oil fuel tanks is to be such that there is no exposed horizontal section at the bottom that could be exposed to a fire. Other fire protection arrangements for oil fuel tanks will be specially considered. For details of fire protection requirements see Section 3-4-1.

All internal surfaces of FRP tanks are to be covered with chopped strand mat weighing at least 600 g/m² (2 oz/ft²). This covering is to be in addition to the scantlings required by these Rules. A suitable coating is to be applied to this covering to prevent the contents of the tank from impregnating the surrounding laminates. The sides, tops, and baffles of integral tanks are to have all connections taped on both sides. Fresh water tanks are to be coated with a non-toxic and non-tainting coat of resin that is recommended by the resin manufacturer for potable water tanks. Where outfit items are to be laminated to the tank surface, the heavy coating of resin is to be applied afterwards and the laminated brackets sealed to prevent the ingress of moisture. The scantlings of integral oil fuel and water tanks are to be in accordance with Section 3-2-3 and Section 3-2-4. Integral tanks are to be tested in accordance with 3-7-1/3.5.7 TABLE 1.
PART 3
CHAPTER 2 Hull Structures and Arrangements
SECTION 6 Arrangement, Structural Details and Connections

1 Structural Details

1.1 Aluminum and Steel

1.1.1 General
Structural details are to be designed and constructed to minimize hard spots, notches and other structural discontinuities. Openings in webs, girders and other structural internal members are to be arranged clear of concentrated loads or areas of high stresses; slots in transverses and girders for longitudinals or beams in such locations are to be fitted with collars. Care is to be taken to ensure structural continuity; sharp corners and abrupt changes in section are to be avoided; toes of brackets and ends of members are not to terminate on plating without attachment to an adjacent member, unless specially approved.

1.1.2 Longitudinals
Deck, bottom and inner bottom longitudinals are in general to be continuous unless specially approved otherwise, but in way of bulkheads they may be intercostal provided continuity of strength and end fixity are maintained by the end brackets. The ends of all internal structural members are to provide end-fixity and load transmission to the supporting member. Departures from this may be considered where the alternative structure has equivalent strength. See 3-2-5/1

1.1.3 Girders and Transverses
Girders and transverses are to have depths not less than twice the depth of slots for longitudinals and beams or other openings. Transverses are to be arranged as continuous web rings, girders are to be aligned with stiffeners at bulkheads, alternative arrangements that provide fixity at the ends of transverses and girders will be specially considered.

1.1.4 Openings
Access and lightening holes with suitably radiused corners are to be arranged as necessary and clear of areas of load concentration or high stresses. Their depths and lengths are generally not to exceed respectively, 0.5 and 0.75 the depth of the members.

1.1.5 Limber Holes
Drains or limber holes are to be provided in non-tight structure to prevent the accumulation of liquids. Vent pipes are to be arranged to prevent over pressuring of tanks. (See 4-4-3/9.1) Holes are to be located to ensure complete drainage of all non-tight voids, bays, or pockets formed by structure. The holes are not to be located at points of high stress, such as the intersection of members. Limber holes are to be half round at the edge, or round if not at the edge, of the structure that is to be drained. The diameter of drain or limber hole is not to be greater than 20% of the depth of the member.

1.1.6 Bi-metallic Connections
In aluminum construction, where bi-metallic connections are unavoidable, suitable insulation, such as gaskets, washers, sleeves, and bushings, are to be provided. The faying surfaces between mechanically fastened metal components, except machinery foundation shims, are to be protected
by the use of a bedding compound. Stainless steel fasteners may be joined directly. See also 3-2-13/3.

1.3 Fiber Reinforced Plastic

1.3.1 General

Structural continuity is to be maintained and where changes in thickness or structural section occur, they are to be gradual to prevent notches, hard spots and other structural discontinuities. The requirements of 3-2-6/1.3.4 and 3-2-6/1.3.5, below, and of 3-2-6/3 and 3-2-6/5 are for the basic laminate given in Part 2, Chapter 6. Special consideration will be given where other laminates or resins are used. The ends of all internal structural members are to provide end-fixity and load transmission to the supporting member. Departures from this may be considered where the alternative structure has equivalent strength.

1.3.2 Changes in Laminate Thickness

A gradual taper is to be used for all changes in laminate thickness. Where the construction changes from sandwich laminate to a solid laminate, the thickness of the core material is in general, to be reduced by a gradual taper of not less than 2:1.

1.3.3 Openings, Holes and Raw Edges

Access and lightening holes with suitably radiused corners are to be arranged as necessary and clear of areas of load concentration or high stresses. Their depths and lengths are generally not to exceed, respectively, 0.5 and 0.75 times the depths of the members. Air and limber holes are to be in accordance with 3-2-6/1.1.5.

All exposed edges in way of cuts or holes in FRP single-skin laminates are to be sealed with resin. Edges of sandwich panels and edges of holes in sandwich panels are to be covered with one ply of glass cloth lapped no less than 25 mm (1 in.) onto each face of the laminate. The cloth is to be completely saturated with resin.

Ferrules installed in sandwich panels or stiffeners for drains or wire penetrations are to be set in bedding compound.

All hatch openings are to be supported by a system of transverse and longitudinal stiffeners.

1.3.4 Piping and Wiring in Foam

Piping or wiring passing through foam-filled spaces is to be installed in PVC tubing. The pipe is to be arranged such that water will not become trapped. The ends of the plastic tubing are to be joined to adjacent structure with resin impregnated mat. See 3-2-6/1.3.4 FIGURE 1.

FIGURE 1

Piping or Opening through Foam Filled Space

---

**ABS RULES FOR BUILDING AND CLASSING HIGH SPEED CRAFT • 2019**

121
1.3.5 Stiffeners

1.3.5(a) General.
Stiffeners, frames, girders, deck beams, bulkhead stiffeners, etc. used to support FRP panels may be entirely of FRP, FRP laid over nonstructural cores or forms, or composites of FRP or other approved structural materials.

1.3.5(b) Stiffeners without effective Cores or with Nonstructural Cores.
Stiffeners without cores or with cores not indicated in 2-6-1/5.5 TABLE 1 are to conform to 3-2-6/1.3.5(b) FIGURE 2, and the thickness of the crown and web of the stiffeners is to be not less than obtained from the following equations:

\[
t_1 = \frac{w}{20} \quad \text{mm (in.)}
\]

\[
t = \frac{h}{30} \quad \text{mm (in.)}
\]

where

\[
t_1 = \text{thickness of stiffener crown, in mm (in.)}
\]

\[
t = \text{thickness of stiffener webs, in mm (in.)}
\]

\[
w = \text{width of stiffener crown, in mm (in.)}
\]

\[
h = \text{height of stiffener webs, in mm (in.)}
\]

Where the stiffeners are of laminates with properties differing from the basic laminate, the thickness is to be modified by the factor:

\[
7.7 \sqrt{\frac{C}{E}}
\]

where

\[
E = \text{compressive modulus of proposed laminate, in kg/cm}^2 \text{ (psi)}
\]

\[
C = \text{ultimate compressive strength of proposed laminate, in kg/cm}^2 \text{ (psi)}
\]

Where polyvinylchloride, balsa, or other approved core material is used, thicknesses less than given above may be accepted provided the buckling stresses of the stiffener skins comply with the buckling stress criteria in 3-2-3/5.7.4.

Hat-section stiffeners constructed by laying FRP over premolded FRP forms (3-2-6/1.3.5(b) FIGURE 3) are to conform with 3-2-6/1.3.5(b) FIGURE 2 and the above equations; the premolded forms may be considered structurally effective if their physical properties are at least equal to those of the overlay laminates.
Premolded stiffeners bonded to the laminates with FRP angles, flanges or tapes (3-2-6/1.3.5(b) FIGURE 4) are also to conform to 3-2-6/1.3.5(b) FIGURE 2 and the above equations. The thickness of each bonding angle flange or tape is to be not less than the thickness of the webs of the stiffener, and the legs of the bonding angle, flange or tape are to be of equal length in accordance with 3-2-6/5. Joints in premolded stiffeners are to be scarphed and spliced or otherwise reinforced to maintain the fill strength of the stiffeners.

The thickness may be less than obtained from the above equation if these members are suitably stiffened and provided with adequate lateral stability. The required minimum flange or tape laps onto such members, as shown in 3-2-6/1.3.5(b) FIGURE 2, if greater than 50 mm (2 in.), need not exceed 10t.
1.3.6 Girders and Longitudinal Frames

Girders and longitudinal frames are to be continuous through floors and web frames. Except in way of integral-tank end bulkheads, girders and longitudinal frames are also to be continuous through transverse bulkheads. Where such members are intercostal, attention is to be given to minimizing structural discontinuities. Where transverse structure is cut out in way of continuous members, the cut out is to be closed as to maintain the required tightness.

An acceptable type of continuous girder and longitudinal-frame FRP connection is shown in Figure 5. The laps of the connections onto the supporting structure are to be not less than the overall widths of the structural members including flanges, and the thicknesses of the connections are to be not less than the thicknesses of the structural-member flanges or tapes.

1.3.7 Engine Foundations

Engine bed fittings are to be of thicknesses and widths appropriate to the holding down bolts such that there is a close and accurate fit between the fittings and the engine girder.
Where the engine girders are a non-molded surface, the fittings are to be set in filled resin or mat. On a molded surface where the contours on the girders match the contours on the fitting, the fittings are to be set in a structural adhesive of a filled resin.

The fittings are to be bolted through the webs of the girders. A compression sleeve constructed of stainless steel or FRP is to be fitted in way of the through bolts. The area of the girder that is connected to the fitting is to have a high density insert in way of the faying surfaces. The insert is to extend 25 mm (1 in.) in all directions beyond the connection. If the size of the insert is less than 150 cm$^2$ (24 in$^2$) a compound consisting of three parts phenolic or glass microballons, two parts resin, and one part milled glass fibers, by volume, may be used. A doubler consisting of one ply of mat and two plies of structural laminates are to be added to each face of the cored laminate. The doubler is to extend no less than 75 mm (3 in.) beyond the high density foam insert.
1.3.8 Deck Fittings

Deck fittings, such as cleats and chocks, are to be bedded in sealing compound, structural adhesive, or gasketed, through-bolted, and supported by either oversize washers or metal, plywood or wood backing plates, as shown in 3-2-6/1.3.8 FIGURE 7. Where washers are used, the laminate in way of the fittings is to be increased at least 25% in thickness. In no case is the fitting to impair the strength or tightness of the structure.
1.3.9 Through Hull Penetrations

Generally all through hull penetrations below the deepest draft design waterline are to be formed by solid FRP laminates, as shown in 3-2-6/1.3.9 FIGURE 8. When sandwich construction is used for the hull, the core material is to be completely sealed off from the through hull penetration, as shown in 3-2-6/1.3.9 FIGURE 9. All through hull penetrations are to be taped on both sides of the penetration. The penetration is to be set in a bedding compound.
1.3.10 Boundary Angles, Flanges or Tapes

1.3.10(a) FRP to FRP.
Secondary bonding of FRP components by means of double boundary angles, flanges or tapes is to be in accordance with Part 2, Chapter 6. Typical boundary angles for FRP components are shown in FIGURE 10. At the end connections of sandwich laminates, the core shear strength is to be effectively developed. The bulkheads are to be set into a foam insert, slow curing polyester putty, a microballon mixture or other approved material. The thickness of each boundary angle, flange or tape having similar strength to the members being connected is to be not less than obtained from the following:

1.3.10(b) Single-skin to Single-skin.
One-half the thickness of the thinner of the two laminates being joined.

1.3.10(c) Sandwich to Sandwich.
The greater of the mean thicknesses of the skins of the sandwich panels being attached.

1.3.10(d) Sandwich to Single Skin.
Either one-half the thickness of the single-skin laminate or the mean thickness of the skins of the sandwich panel being attached, whichever is less.

The thickness of each FRP-to-FRP boundary angle also is to be not less than obtained from the following equation:

\[ t = 0.105L + 1.11 \text{ mm} \]
\[ t = 0.00133L + 0.044 \text{ in.} \]

where

\[ L \] = length, in m (ft), as defined in 3-1-1/3, need not be taken as more than 46.6 m (153 ft).

The width of each flange, not including end taper, is to be not less than 10 times the thickness given above, including the end taper, 13 times the thickness given above, and in general not less than 50 mm (2 in.).
3 Welded and Mechanical Connections

3.1 Steel and Aluminum

3.1.1 General
Components may be fastened by either welding or rivets. For welding, see Section 3-2-13 and Part 2, Chapters 4 and 5.

3.1.2 Expanding Rivets
Rivets of the expanding type (blind or “pop” rivets) may be used for lightly loaded connections where lack of accessibility prohibits the use of through fastenings. Such rivets are not to be used for joining components having a total thickness exceeding 12.5 mm (0.50 in.), and are not to be used for joining decks to hulls except as temporary or unstressed fastenings installed for the sake of convenience or speed during assembly.

3.1.3 Conventional Rivets
Conventional rivets, where used, are to be subject to special consideration, and are to be of the cold-driven type. Washers, essentially of the same material as the rivets, are to be installed under both the heads and the points.

3.3 Fiber Reinforced Plastic

3.3.1 General
Components may be fastened with bolts, machine screws, or self-tapping screws. Where machine screws or self-tapping screws are used, they are not to have countersunk heads. Shanks of all threaded fastenings are to be long enough to pass through the joints, by at least one thread beyond the top of the nut or plastic locking element. Excessive protrusion is to be avoided, and where the threaded end of the fastener is accessible, and the excess length can constitute a hazard, the excess
length is to be removed. Washers are not to be used for the sole purpose of lessening thread protrusion. When it is necessary to reduce the length of thread protrusion, excess length is to be removed without damaging the threads and the bolts dressed to remove rough edges. Where watertight joints are required, suitable sealants or bedding compounds are to be used in addition to the fastenings. All threaded fasteners are to be stainless steel unless alternatives are specifically allowed by the Naval Administration. Sizes and specifications are to be indicated on the submitted plans. The diameter of a fastening is not to be less than the thickness of the thinner component being fastened, with a minimum diameter of 8 mm (0.315 in.). Where hardware is predrilled for fastener sizes that are less than specified above, the size of the fastener used is to match the size of the predrilled holes.

3.3.2  Bolts and Machine Screws

Bolts or machine screws are to be used where accessibility permits. The diameter of each fastener is to be at least equal to the thickness of the thinner component being fastened. Bolts and machine screws less than 8 mm (0.315 in.) in diameter are not to be used. Where \( d \) is the fastener diameter, fastener centers are to be spaced at a minimum of \( 3d \) apart and are to be set in from edges of laminates a minimum of \( 3d \).

Generally in fiber reinforced plastic construction, all bolted connections are to be made through solid fiber reinforced plastic inserts. Where this is not possible, all low density core material is to be replaced with a structurally effective insert. Diameters of fastening holes are not to exceed fastening diameters by more than 0.5 mm (0.02 in.) for bolts less than or equal to 18 mm (0.71 in.) in diameter and 1 mm (0.39 in.) for bolts greater than 18 mm (0.71 in.) in diameter. Elongated and oversize holes are permitted where necessary for adjustment or alignment.

Washers or backing plates are to be installed under all fastening heads and nuts that otherwise would bear on laminates. Washers are to measure not less than 2.25\( d \) in outside diameter and 0.1\( d \) in thickness. Nuts are to be either of the self-locking type, or other effective means are to be provided to prevent backing off. Mechanical thread locking devices and methods such as lockwashers, either spring, tooth, or tab type, peening wiring, or thread upset after assembly are not to be used.

Bolted connections are, in general, to be bonded along all mating surfaces to insure the tightness of the structure using an accepted structural adhesive, applied in accordance with the manufacturer’s requirements.

In general, all structural, bolted connections are to use threads of bolts in accordance with the requirements in the following table:

<table>
<thead>
<tr>
<th>Location</th>
<th>Pitch (^{(1)})</th>
</tr>
</thead>
<tbody>
<tr>
<td>Watertight connections below design waterline</td>
<td>10( d )</td>
</tr>
<tr>
<td>Connections in hull above design waterline to deck</td>
<td>15( d )</td>
</tr>
<tr>
<td>Hull to deck connections, bonded with approved structural adhesive</td>
<td>15( d )</td>
</tr>
<tr>
<td>Connections in deckhouses</td>
<td>20( d )</td>
</tr>
<tr>
<td>Deckhouse to deck connection, bonded with approved structural adhesive</td>
<td>15( d )</td>
</tr>
<tr>
<td>Minimum distance between reeled lines of bolts</td>
<td>3( d )</td>
</tr>
</tbody>
</table>

Notes:

1. \( d \) is the diameter of the bolt.
2. Internal boundary sealing angle is to be provided for all locations.
All structural, single line, bolted connections without adhesive bonding are to be in accordance with the requirements in the following table:

<table>
<thead>
<tr>
<th>Location</th>
<th>Pitch (1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manhole covers to fuel tanks</td>
<td>6d</td>
</tr>
<tr>
<td>Manhole covers to water tanks</td>
<td>8d</td>
</tr>
<tr>
<td>Covers to void tanks/cofferdams</td>
<td>10d</td>
</tr>
<tr>
<td>Bolted access hatches in decks</td>
<td>10d</td>
</tr>
<tr>
<td>Bolted watertight door frames</td>
<td>8d</td>
</tr>
<tr>
<td>Window frames</td>
<td>8d</td>
</tr>
</tbody>
</table>

Note:

1. d is the diameter of the bolt.

Bolt holes are to be drilled, without undue pressure at breakthrough, having a diametric tolerance of two percent of the bolt diameter. Where bolted connections are to be made watertight, the hole is to be sealed with resin and allowed to cure before the bolt is inserted. In areas of high stress or where unusual bolting configurations, on the basis of equivalence with the above requirements, are proposed, testing may be required.

3.3.3 Self-tapping Screws

In general, no self-tapping screws are to be used in fiber reinforced plastic construction. Self-tapping screws having straight shanks may be used for non-structural connections where lack of accessibility prohibits the use of through fastenings. Where used, self-tapping screws are to have coarse threads.

3.5 Backing Bars and Tapping Plates

The requirements for backing plates and bars will be individually considered, on the basis of the loading imposed, details of which are to be indicated on the submitted plans. Metal plates and bars are to be suitably protected against corrosion. Tapping plates may be encapsulated within the laminate, laminated to or bolted to the structure. Tapping plate edges or corners are to be suitably rounded.

5 FRP Deck-to-Hull Joints

5.1 Weather Joints

The connection is to develop the strength of the deck and shell laminate, whichever is stronger, by either a bolted or bonded connection.

Where flanges are used, the hull flanges are to be equal in thickness and strength to the hull laminates and the deck flanges are to be equal in strength and thickness to the deck laminates. Where bolts are used to develop the required strength of the connection, the faying surfaces are to be set in bedding compound, polyester putty, or other approved material. Minimum widths of overlaps, minimum bolt diameters, and maximum bolt spacing are to be in accordance with 3-2-6/5.3 TABLE 1. Intermediate values may be obtained by interpolation.

FRP bonding angles, where used, are to have flanges of the same strength and of at least one-half the thickness of single skin hull or deck laminate. On sandwich laminates, they are to have the same strength and thickness as the skin of a sandwich laminate, based on the thicker of the two laminates being connected. The widths of the flanges are to be in accordance with the widths of overlaps in 3-2-6/5.3 TABLE 1.
Calculations supporting the geometry of the deck-to-hull joint are to be submitted for craft over 60 m (200 ft) in length.

Each joint is to be protected by a guard, molding, fender, or rail cap of metal, wood, rubber, plastic, or other approved material. The size and ruggedness of this protective strip are to be consistent with the severity of the service for which the craft is intended. The strip is to be installed in such a manner that it may be removed for repair or replacement without endangering the integrity of the deck-to-hull joint.

5.3 Interior Joints

Interior decks are to be connected to the hull by shelves, stringers, or other structural members on both sides by FRP tapes. The connection is to effectively develop the strength of the interior deck. The fit-up between the parts are typically not to exceed 5 mm (0.2 in.). The interior deck is to be bedded in syntactic foam or filled resin during assembly and prior to tabbing.

7 **FRP Shell Details**

7.1 **Keels**

Plate keels are to be not less than shown in 3-2-6/7.1 FIGURE 12a and 3-2-6/7.1 FIGURE 12b, and vertical keels or skegs are to be not less than shown in 3-2-6/7.1 FIGURE 13. Keels or skegs are to be adequate for docking loads, which are to be provided by the designer.
7.3 Chines and Transoms
Chines and transoms are to be not less than shown in 3-2-6/Figures 14a through 14d.

CHAPTER 2 Hull Structures and Arrangements

SECTION 7 Keels, Stems, Shaft Struts, and Propeller Nozzles

1 Materials

1.1 Ordinary Strength Steels
The requirements in the following subsections are based upon ordinary strength steel. For higher strength steels and aluminum alloys see 3-2-7/1.3.

1.3 High Strength Steels and Aluminum Alloys
Unless otherwise specified, the required section modulus and inertia for high strength steels and aluminum alloys are as follows:

\[ SM = SM_s Q \]
\[ I = I_s E_s / E_o \]

where

\[ SM, I \] = required section modulus and inertia. Unless specifically stated otherwise, the properties about the minor axis (axis perpendicular to \( h \) or \( w \)) are to be used.

\[ SM_s, I_s \] = section modulus and inertia obtained from the dimensions given for ordinary strength steel.

\[ Q \] = as defined in 3-2-1/1.1.1

\[ E_s = 2.06 \times 10^5 \text{ N/mm}^2 \] (21 × 10^3 kgf/mm^2, 30 × 10^6 psi)

\[ E_o \] = modulus of the material being considered in N/mm^2 (kgf/mm^2, psi)

Use of materials other than steel or aluminum will be specially considered.

1.5 Fiber Reinforced Plastic
For fiber reinforced plastic hulls, keels and skegs are to have proportions as indicated in 3-2-6/5.3 FIGURE 11 and 3-2-6/Figure 12.

3 Keels

3.1 Bar Keels
Where bar keels are fitted the thickness and depth is not to be less than obtained from the following equations:

\[ t = 0.625L + 12.5 \text{ mm} \]

\[ t = 0.0075L + 0.50 \text{ in.} \]

\[ h = 1.46L + 100 \text{ mm} \]
\[ h = 0.0175L + 4 \text{ in.} \]

where

\[ t = \text{thickness, in mm (in.)} \]
\[ h = \text{depth, in mm (in.)} \]
\[ L = \text{length of craft, in m (ft), as defined in Section 3-1-1} \]

Thicknesses and depths other than given above are acceptable provided the section moduli and moments of inertia about the transverse horizontal axis are not less than given above.

### 3.3 Plate Keels

The thickness of the steel plate keel throughout the length of the craft is to be not less than the bottom shell required in Section 3-2-3.

### 5 Stems

#### 5.1 Bar Stems

Where bar stems are fitted the thickness and depth is not to be less than obtained from the following equations:

\[ t = 0.625L + 6.35 \text{ mm} \]
\[ t = 0.0075L + 0.25 \text{ in.} \]
\[ w = 1.25L + 90 \text{ mm} \]
\[ w = 0.015L + 3.5 \text{ in.} \]

where

\[ t = \text{thickness, in mm (in.)} \]
\[ w = \text{width, in mm (in.)} \]
\[ L = \text{length of craft, in m (ft), as defined in 3-1-1/3} \]

This thickness and width is to be maintained between the keel and design load waterline. Above the designed load waterline they may be gradually reduced until the area at the head is 70% of that obtained from the equations.

Thicknesses and widths other than given above are acceptable provided the section moduli and moments of inertia about the longitudinal axis are not less than above. The thickness of the bar stem in general should also not be less than twice the shell thickness.

#### 5.3 Plate Stems

Where plate stems are used, they are not to be less in thickness than the bottom shell plating required in 3-2-3/1 and 3-2-3/3, where \( s \) is the frame spacing, or 610 mm (24 in.) if greater. Plate stems are to be suitably stiffened.

### 7 Stern Frames

Craft that are fitted with stern frames, shoe pieces, rudder horns, and rudder gudgeons are to meet the applicable requirements in Section 3-2-13 of the *Rules for Building and Classing Marine Vessels*.
9  Shaft Struts

9.1  General
Tail-shaft (propeller-shaft) struts where provided may be of the V or I type. The following equations are for solid struts having streamline cross-sectional shapes. For struts other than ordinary strength steel see 3-2-7/1.3. For hollow section and non-streamlined struts, the equivalent cross sectional area, inertia, and section modulus (major axis) are to be maintained. For a streamlined cross-section strut, the inertia about the longitudinal axis is $wt^3/25$ and the section modulus about the same axis is $wt^2/12.5$. Generally each leg of a “V” strut are to have similar cross section. Alternative methods for the determination of “V” strut requirements can be found in Appendix 3-2-A3.

9.3  V Strut

9.3.1  Width
The width of each strut arm is not to be less than obtained from the following equation:

$$w = 2.27D$$

where

- $w =$ width of strut (major axis), in mm (in.)
- $D =$ required diameter of ABS Grade 2 tail shaft, in mm (in.). (see Section 4-3-1)

9.3.2  Thickness
The thickness of the strut is not to be less than obtained from the following equation:

$$t = 0.365D$$

where

- $t =$ thickness of strut (minor axis), in mm (in.)
- $D =$ required diameter of ABS Grade 2 tail shaft, in mm (in.)

Where the included angle is less than 45 degrees, the foregoing scantlings are to be specially considered.

9.5  I Strut

9.5.1  Width
The width of the strut arm is not to be less than obtained from the following equation:

$$w_1 = 3.22D$$

where

- $w_1 =$ width of strut (major axis) in mm (in.)
- $D =$ diameter of tail shaft in mm (in.)

9.5.2  Thickness
The thickness of the strut is not to be less than obtained from the following equation:

$$t_1 = 0.515D$$

where
9.7 Strut Length
The length of the longer leg of a V strut or the leg of an I strut, measured from the outside perimeter of the strut barrel or boss to the outside of the shell plating, is not to exceed 10.6 times the diameter of the tail shaft. Where this length is exceeded, the width and thickness of the strut are to be increased, and the strut design will be given special consideration. Where strut length is less than 10.6 times required tailshaft diameter, the section modulus of the strut may be reduced in proportion to the reduced length, provided the section modulus is not less than 0.85 times Rule required section modulus.

9.9 Strut Barrel
The thickness of the strut barrel or boss is to be at least one-fifth the diameter of the tail shaft. The length of the strut barrel or boss is to be adequate to accommodate the required length of propeller-end bearings. Strut barrels constructed of aluminum are not subject to the corrections required by 3-2-7/1.3.

10 Skegs and Other Hull Appendages (2015)
Craft fitted with skegs and other permanent hull appendages are to comply with the following:

i) The anticipated operational loadings under all craft operations (docking loads, hydrodynamic forces, and etc., as applicable) are to be submitted for ABS review.

ii) All skegs and other permanent hull appendages are to be attached to the shell plate by means of double continuous fillet welds in accordance with 3-2-13/1.5 using a weld factor \( C = 0.5 \) DC. Appendage structure is to be aligned or reinforced with internal hull structural members.

iii) Thickness of shell plating in way of an appendage is to be increased in accordance with 3-2-3/1.1.

iv) Where a closing plate prohibits the inspection of a void space or joint that is integral to the shell plating, access ports and drain plugs are to be provided in way of this space.

v) In the case of large continuous skegs or other similar hull appendages, direct analysis may be requested by ABS in order to validate stress interaction effects with the hull girder.

vi) Where the appendages designed to shear off in the event of impact, calculations for the appendage are to be submitted and subject to special consideration.

11 Propeller Nozzles

11.1 Application
The requirements in this section are applicable for propeller nozzles with inner diameter \( d \) of 5 meters (16.4 feet) or less. Nozzles of larger inner diameter are subject to special consideration with all supporting documents and calculations submitted for review.

11.3 Design Pressure
The design pressure of the nozzle is to be obtained from the following:

\[
p_d = 10^{-6} \cdot c \cdot \varepsilon \left( \frac{N}{A_p} \right)\quad \text{N/mm}^2(\text{kgf/mm}^2, \text{psi})
\]

where

\[
c = \text{coefficient as indicated in 3-2-7/11.3 TABLE 1}
\]

\[
\varepsilon = \text{coefficient as indicated in 3-2-7/11.3 TABLE 2, but not to be taken less than 10}
\]
\[ N = \text{maximum shaft power, in kW (hp)} \]
\[ A_p = \text{propeller disc area} \]
\[ = D^2 \frac{\pi}{4} \text{, in } \text{m}^2 (\text{ft}^2) \]
\[ D = \text{propeller diameter, in m (ft)} \]

11.5 **Nozzle Cylinder**

11.5.1 **Shell Plate Thickness**

The thickness of the nozzle shell plating, in mm (in.), is not to be less than:

\[ t = t_o + t_c \], but not to be taken less than 7.5 (0.3) mm (in.)

where

\[ t_o = \text{thickness obtained from the following formula:} \]
\[ = c_n \cdot S_p \cdot \sqrt{p_d K_n} \text{ mm (in.)} \]
\[ c_n = \text{coefficient as indicated in 3-2-7/11.5.1 TABLE 3} \]
\[ S_p = \text{spacing of ring webs, in mm (in.)} \]
\[ p_d = \text{nozzle design pressure, in N/mm}^2 (\text{kgf/mm}^2, \text{psi}), \text{as defined in 3-2-7/11.3} \]
\[ t_c = \text{corrosion allowance determined by 3-2-7/11.5.1 TABLE 4} \]
\[ K_n = \text{nozzle material factor as defined in 3-2-8/1.3} \]

where

$$b_2 = \left( \frac{t_o}{\sqrt{1/n}} + 5 \right) \times 10^{-1} \text{ mm or } b_2 = \left( \frac{t_o}{\sqrt{1/n}} + 0.2 \right) \times 10^{-1} \text{ in.}$$

11.5.2 Internal Diaphragm Thickness

Thickness of nozzle internal ring web is not to be less than the required nozzle shell plating for Zone 3.

11.7 Nozzle Section Modulus

The minimum requirement for nozzle section modulus is obtained from the following formula:

$$SM = d^2 b V_d^2 Q n \text{ cm}^3 \text{ (in)}$$

where

- $d$ = nozzle inner diameter, in m (ft)
- $b$ = nozzle length, in m (ft)
- $V_d$ = design speed in ahead condition, in knots, as defined in 3-2-8/3.1
- $Q$ = reduction factor conditional on material type
  - = 1.0 for ordinary strength steel
  - = 0.78 for H32 strength steel
  - = 0.72 for H36 strength steel
  - = 0.68 for H40 strength steel
  $Q$ factor for steel having yield strength other than above is to be specially considered
- $n$ = nozzle type coefficient taken equal to 0.7 (0.0012) for fixed nozzles
FIGURE 1

\[ = \frac{b}{8} \]
\[ = \frac{b}{8} \cos \alpha + \frac{d}{2} \tan \alpha \]
where Zone 2 center plane and propeller disc center plane coincide as shown in 3-2-7/11.7 FIGURE 1(a);
where \( \alpha \) is the tilt angle between the Zone 2 and propeller disc center planes, as shown in 3-2-10/19.1 FIGURE 1(b);

Zone 3 zone of nozzle inner and outer skin covering the tail vicinity, from aft end of Zones 2 to the aft end of Zone 4
Zone 4 zone of nozzle outer skin from the leading edge to the fore end of Zone 3

11.9 Welding Requirement
The inner and outer nozzle shell plating is to be welded to the internal stiffening ring webs with double continuous welds as far as practicable. Plug/slot welding is prohibited for the inner shell, but may be accepted for the outer shell plating, provided that the nozzle ring web spacing is not greater than 350 mm (13.8 in.)

13 Propulsion Improvement Devices (PID) as Hull Appendages (2017)

13.1 Application Scope
The requirements in this Subsection are applicable for Propulsion Improvement Devices (PID) hull appendages including wake equalizing and flow separation alleviating devices (such as spoilers, wake
equalizer, stern tunnels, pre-swirl fins, stators, and pre-swirl ducts) and post swirl devices (such as rudder thrust fins, post swirl stators, and rudder bulbs) that are permanently affixed to the hull structure.

13.3 Plans and Documentation (2019)

The following plans and details are to be submitted for approval, while the calculations are to be submitted for reference:

i) Drawings and plans covering the detailed design of the structural components, including the end connections and attachment to the hull structure;

ii) Information on material properties and welding details, such as scantlings of the welded connection and welding detail and size;

iii) Calculations to validate the design of the PID and the supporting foundations interior to the craft. The calculations are to consider strength, fatigue and vibration, due to hydrodynamic lift and drag loads, in both the ahead and astern conditions. However, depending on the type of PID (such as rudder bulbs, etc.) the calculation may consider the strength only.

13.5 Design and Arrangement

The following requirements are to be complied with for the propulsion improvement devices as outlined in 3-2-7/13.1. Devices of novel concept are to be specially considered with all the related drawings and documents submitted:

i) The structural materials are to be compatible with the mechanical and chemical properties of the hull strake to which it is attached. Examples of such design considerations are to have adequate structural strength for load bearing/transferring and acceptable galvanic potential between materials to reduce the risk of galvanic corrosion.

ii) PID end connections are to have a suitable transition for the particular application and to be effectively terminated in way of internal stiffening members.

13.7 Structural End Connection

Welded end connections of device structural component to the hull are to be designed and constructed in accordance with the following:

i) Welding at the connection is to be full penetration and is to be in accordance with Section 2-4-1 of the ABS Rules for Materials and Welding (Part 2) and Section 3-2-13, as applicable.

ii) Nondestructive volumetric and surface examinations are to be performed on the welds of the connection plates and the shell penetration. 100% Magnetic Testing (MT) and at least 10% Ultrasonic Testing (UT) is to be carried out on the welds of the connection plates and the shell penetration.
CHAPTER 2 Hull Structures and Arrangements

SECTION 8 Rudders and Steering Equipment

1 General

1.1 Application (1 July 2016)

Requirements specified in this Section are applicable to:

i) Ordinary profile rudders described in 3-2-8/3 TABLE 1A with rudder operating angle range from $-35^\circ$ to $+35^\circ$.

ii) High-lift rudders described in 3-2-8/3 TABLE 1B, the rudder operating angle of which might be exceeding $35^\circ$ on each side at maximum design speed.

iii) Other steering equipment other than rudders identified in this section.

Rudders not covered in 3-2-8/3 TABLE 1A nor in 3-2-8/3 TABLE 1B are subject to special consideration, provided that all the required calculations are prepared and submitted for review in full compliance with the requirements in this Section. Where direct analyses adopted to justify an alternative design are to take into consideration all relevant modes of failure, on a case by case basis. These failure modes may include, amongst others: yielding, fatigue, buckling and fracture. Possible damages caused by cavitation are also to be considered. Validation by laboratory tests or full scale tests may be required for alternative design approaches.

Special consideration will be given to aluminum rudder stocks and fiber reinforced plastic rudders and rudder stocks. Material specifications are to be listed on the plans.

1.3 Materials for Rudder, Rudder Stock and Steering Equipment (1 July 2015)

Rudder stocks, pintles, coupling bolts, keys and other steering equipment components described in this Section are to be made from material in accordance with the requirements of Chapter 1 of the ABS Rules for Materials and Welding (Part 2), 3-1-2/1.1 TABLE 2, and particularly:

i) The Surveyor need not witness material tests for coupling bolts and keys.

ii) The surfaces of rudder stocks in way of exposed bearings are to be of noncorrosive material.

iii) Material properties of dissimilar parts and components in direct contact with each other are to be submitted for review of compatibilities, such as galvanic potential.

iv) Material factors of castings and forgings used for the shoe piece ($K_g$), horn ($K_h$), stock ($K_s$), bolts ($K_b$), coupling flange ($K_f$), pintles ($K_p$), and nozzles ($K_n$) are to be obtained for their respective material from the following equation:

$$K = \left(\frac{n_y}{Y}\right)^e$$

where
\[ n_y = 235 \text{ N/mm}^2 (24 \text{ kgf/mm}^2, 34000 \text{ psi}) \]

specified minimum yield strength of the material, in N/mm\(^2\) (kgf/mm\(^2\), psi), but is not to be taken as greater than 0.7\(U\) or 450 N/mm\(^2\) (46 kgf/mm\(^2\), 65000 psi), whichever is less.

\[ Y = \text{minimum tensile strength of material used, in N/mm}^2 (\text{kgf/mm}^2, \text{psi}) \]

\[ U = 1.0 \text{ for } Y \leq 235 \text{ N/mm}^2 (24 \text{ kgf/mm}^2, 34000 \text{ psi}) \]

\[ = 0.75 \text{ for } Y > 235 \text{ N/mm}^2 (24 \text{ kgf/mm}^2, 34000 \text{ psi}) \]

For craft receiving the OE notation as defined in 1-1-3/5 TABLE B, \(Y\) may be specially considered.

1.5 Expected Torque

The torque considered necessary to operate the rudder in accordance with 4-3-3/5.4 is to be indicated on the submitted rudder or steering gear plan. See 4-3-3/1.5 and 3-2-8/5.7.

Note that this expected torque is not the design torque for rudder scantlings.

1.7 Rudder Stops

Strong and effective structural rudder stops are to be fitted. Where adequate positive mechanical stops are provided within the steering gear in accordance with 4-3-3/5.1, structural stops will not be required.

3 Rudder Design Force

Rudder force, \(C_R\), upon which rudder scantlings are to be based, is to be obtained from equation described either in 3-2-8/3.1 or 3-2-8/3.3 as applicable. Where for the ordinary rudders the rudder angle, \(\phi\), exceeds 35°, the rudder force, \(C_R\), is to be increased by a factor of 1.74 sin (\(\phi\)).

3.1 Rudder Blades without Cutouts (2014)

Where the rudder profile can be defined by a single quadrilateral, the rudder force is to be obtained from the following equation.

\[ C_R = nk_k k_e A V_R^2 \text{ kN(\text{tf, Ltf})} \]

where

\[ n = 0.132 (0.0135, 0.00123) \]

\[ k_R = \left( \frac{b^2}{A_t} + 2 \right) / 3 \text{ but not taken more than 1.33} \]

\[ b = \text{mean height of rudder area, in m (ft), as determined from 3-2-8/3 FIGURE 1A} \]

\[ A_t = \text{sum of rudder blade area, } A, \text{ and the area of rudder post or rudder horn within the extension of rudder profile, in m}^2 (\text{ft}^2) \]

\[ A = \text{total projected area of rudder as illustrated in 3-2-8/3 FIGURE 1A, in m}^2 (\text{ft}^2) \]

For steering nozzles, \(A\) is not to be taken less than 1.35 times the projected area of the nozzle.

\[ k_c = \text{coefficient depending on rudder cross section (profile type) as indicated in 3-2-8/Table 1A and 1B. For profile types differing from those in 3-2-8/Table 1A and 1B, } k_c \text{ is subject to special consideration.} \]

\[ k_e = \text{coefficient as specified in 3-2-8/5.3 TABLE 2} \]

\[ V_R = \text{craft speed, in knots} \]
= for ahead condition $V_R$ equals $V_d$ or $V_{min}$, whichever is greater
= for astern condition $V_R$ equals $V_a$ or $0.5V_d$, or $0.5V_{min}$, whichever is greater

$V_d$ = design speed in knots with the craft running ahead at the maximum continuous rated shaft rpm
and at the summer load waterline

$V_a$ = maximum astern speed in knots

$V_{min}$ = $(V_d + 20)/3$

Where there are any appendages such as rudder bulb fitted on the rudder, its effective areas are to be
included in the area of the rudder blade if significant.

### 3.3 Rudder Blades with Cutouts

This paragraph applies to rudders with cutouts (semi-spade rudders), such that the whole blade area cannot
be adequately defined by a single quadrilateral. See 3-2-8/3 FIGURE 1B. Equations derived in this
paragraph are based on a cutout blade with two quadrilaterals. Where more quadrilaterals are needed to
define the rudder shape, similar rules apply.

The total rudder force described in 3-2-8/3.1 is applicable for rudders with cutout(s), with $A$ being the
summation of sub-quadrilaterals that make up the whole area of the rudder blade. Rudder force distribution
over each quadrilateral is to be obtained from the following equations:

$$C_{R1} = \frac{C_RA_1}{A} \text{ kN(tf, Ltf)}$$
$$C_{R2} = \frac{C_RA_2}{A} \text{ kN(tf, Ltf)}$$

where

$C_R$ and $A$ are as defined in 3-2-8/3.1

$A_1$ and $A_2$ are as described in 3-2-8/3 FIGURE 1B.

### 3.5 Rudders Blades with Twisted Leading-Edge (2014)

This kind of rudder has the leading edge twisted horizontally on the top and bottom of the section that is an
extension of the center of the propeller shaft. For the purpose of calculating design force, twisted rudders
may be distinguished in four categories:

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The projected leading edge of twisted upper and lower blades not lineup to each other</td>
</tr>
<tr>
<td>2</td>
<td>The projected leading edge of twisted upper and lower blades form a straight line</td>
</tr>
<tr>
<td>3</td>
<td>Rudder with twisted leading-edge combined with tail edge flap or fins</td>
</tr>
</tbody>
</table>
| 4        | The twisted leading edge has a smooth continuous wavy contour (no deflector) or the rudder has
multiple section profile types |

Design force for rudder with twisted leading edge is obtained according to the following criteria:

i) For Category 1 rudders as indicated in the above table, design force over upper and lower rudder
blades are obtained from the following equations respectively:
\[ C_{R1} = n k_R k_c A_1 V_R^2 \text{kN(tf, Ltf)} \] for twisted upper rudder blade;

\[ C_{R2} = n k_R k_c A_2 V_R^2 \text{kN(tf, Ltf)} \] for twisted upper rudder blade;

\[ C_R = C_{R1} + C_{R2} \text{kN(tf, Ltf)} \] overall design force;

ii) For Categories 2, 3, and 4, rudder design force indicated in 3-2-8/3.1 is applicable, that is:

\[ C_R = n k_R k_c k_\ell V_R^2 \text{kN(tf, Ltf)} \]

where

\[ n, k_R, k_c, k_\ell, A, \text{ and } V_R \] are as defined in 3-2-8/3.1, (for rudder has multiple section profile types, \( A \) is the whole projected area).

\( A_1 \) and \( A_2 \) are the projected areas of upper and lower blades separated at the deflector cross section, respectively. Where the effective projected area of rudder bulb (if present) forward of rudder leading edge is significant and needs to be counted, the proportioned bulb effective areas are added to \( A_1 \) and \( A_2 \) accordingly.

Values of \( k_c \) for ahead and astern conditions are determined from one of the methods below as applicable, if the type of basic rudder profile is not provided:

a) \( k_c \) is taken from 3-2-8/3 TABLE 1A for twisted rudders of Categories 1 & 2;

b) \( k_c \) is taken from 3-2-8/3 TABLE 1B for twisted rudders of Category 3;

c) \( k_c \) is subjected to special considerations for twisted rudders of Category 4;

d) Shipyard/rudder manufacturers’ submitted \( k_c \) obtained from testing data or calculations may be accepted subject to ABS review of all the supporting documents;

- A_f (see 3-2-8/5.3)
5 **Rudder Design Torque**

5.1 **General**

The rudder design torque, $Q_R$, for rudder scantling calculations is to be in accordance with 3-2-8/5.3 or 3-2-8/5.5 as applicable.

5.3 **Rudder Blades without Cutouts (2014)**

Rudder torque, $Q_R$, is to be determined from the following equation for both ahead and astern conditions.

$$Q_R = Q_{Rr} \ kN-m \ (tf-m, \ Ltf-ft)$$

where
\[ C_R = \text{rudder force as calculated in 3-2-8/3.1} \]
\[ r = c(\alpha - k) \text{ (but not less than 0.1 for ahead condition)} \]
\[ c = \text{mean breadth of rudder area, as shown in 3-2-8/3 FIGURE 1A, in m (ft)} \]
\[ \alpha = \text{coefficient as indicated in 3-2-8/5.3 TABLE 3} \]
\[ k = \frac{A_f}{A} \]
\[ A_f = \text{area of rudder blade situated forward of the centerline of the rudder stock, in m}^2 \text{ (ft}^2\text{), as shown in 3-2-8/3 FIGURE 1A} \]
\[ A = \text{whole rudder area as described in 3-2-8/3.1} \]

Where there are any appendages such as rudder bulb fitted on the rudder, effective areas are to be included in the area of the rudder blade if significant.

#### 5.5 Rudders Blades with Cutouts

This paragraph refers to rudder blades with cutouts (semi-spade Rudders) as defined in 3-2-8/3.3. Equations derived in this paragraph are based on a cutout blade with two quadrilaterals. Where more quadrilaterals are needed to define the rudder shape, similar rules apply.

Total rudder torque, \( Q_R \), in ahead and astern conditions is to be obtained from the following equation:

\[ Q_R = C_{R1}r_1 + C_{R2}r_2 \text{ kN-m (tf-m, Ltf-ft)} \]

but not to be taken less than \( Q_{Rmm} \) in the ahead condition

where
\[ Q_{R\text{min}} = 0.1 C_R (A_1 c_1 + A_2 c_2) / A \]
\[ r_1 = c_1 (\alpha - k_1) \text{ m (ft)} \]
\[ r_2 = c_2 (\alpha - k_2) \]
\[ c_1, c_2 = \text{mean breadth of partial area } A_1, A_2, \text{ from 3-2-8/3 FIGURE 1B} \]
\[ \alpha = \text{coefficient as indicated in 3-2-8/5.3 TABLE 3} \]
\[ k_1, k_2 = A_{1f} / A_1, A_{2f} / A_2 \text{ where } A_{1f}, A_{2f} = \text{area of rudder blade situated forward of the centerline of} \]
\[ \text{the rudder stock for each part of the rudder, as shown in 3-2-8/3 FIGURE 1B} \]

\[ C_R, C_{R1}, C_{R2}, A_1, A_2 \text{ are as defined in 3-2-8/3.3.} \]

5.7 **Rudders with Twisted Leading Edge (2014)**

In general, rudder torque, \( Q_R \), indicated in 3-2-8/5.3 is applicable for rudders with twisted leading edge, where \( C_R \) is obtained from 3-2-8/3.5.

5.9 **Trial Conditions**

The above equations for \( Q_R \) are intended for the design of rudders and should not be directly compared with the torques expected during the trial (see 3-2-8/1.5) or the rated torque of steering gear (see 4-3-3/5.4).

7 **Rudder Stocks**

7.1 **Upper Rudder Stocks (2012)**

The upper stock is that part of the rudder stock above the neck bearing or above the top pintle, as applicable.

\[ S = N_u \sqrt[3]{Q_R K_S} \text{ mm (in.)} \]

where

\[ N_u = 42.0 \ (89.9, 2.39) \]
\[ Q_R = \text{rudder torque, as defined in 5, in kN-m (tf-m, Ltf-m)} \]
\[ K_S = \text{material factor for upper rudder stock, as defined in 3} \]

7.3 **Lower Rudder Stocks (2018)**

In determining lower rudder stock scantlings, values of rudder design force and torque calculated in 3-2-8/3 and 3-2-8/5 are to be used. Bending moments, shear forces, as well as the reaction forces are to be determined from 3-2-8/7.7 and 3-2-8/13.5, and are to be submitted for review. For rudders supported by shoe pieces or rudder horns, these structures are to be included in the calculation model to account for support of the rudder body. Guidance for calculation of these values is given in Appendix 3-2-A1.

The lower rudder stock diameter is not to be less than obtained from the following equation:

\[ S_f = S_{f1} + (A/3)(M/Q_R)^2 \text{ mm (in.)} \]

where
\[ S = \text{upper stock required diameter from 3-2-8/7.1, in mm (in.)} \]
\[ S_f = \text{lower stock required diameter.} \]
\[ M = \text{bending moment at the section of the rudder stock considered, in kN-m (tf-m, Ltf-ft)} \]
\[ Q_R = \text{rudder torque from 3-2-8/5, in kN-m (tf-m, Ltf-ft)} \]

Above the neck bearing a gradual transition is to be provided where there is a change in the diameter of the rudder stock.

The equivalent stress of bending and torsion, \( \sigma_c \) to be assessed from the aforementioned direct calculation in the transition is not to exceed 118 /\( K \) N/mm\(^2\) (12.0 /\( K \) kgf/mm\(^2\), 17100 /\( K \) lbs/in\(^2\)).

\[ \sigma_c = \sigma_b^2 + 3\tau^2 \quad \text{N/mm}^2 (\text{kgf/mm}^2, \text{lbs/in}^2) \]

where
\[ K = \text{material factor as defined in 3-2-8/1.3.} \]
\[ \sigma_b = 10.2 \times 10^6 M/S_f^3 \quad \text{for SI and MKS units} \]
\[ = 270 \times 10^3 M/S_f^3 \quad \text{for US units} \]
\[ \tau_t = 5.1 \times 10^6 Q_R/S_f^3 \quad \text{for SI and MKS units} \]
\[ = 135 \times 10^3 Q_R/S_f^3 \quad \text{for US units} \]

### 7.5 Rudder Trunk and Rudder Stock Sealing (1 July 2019)

**i)** In rudder trunks which are open to the sea, a seal or stuffing box is to be fitted above the deepest load waterline, to prevent water from entering the steering gear compartment and the lubricant from being washed away from the rudder carrier.

**ii)** Where the top of the rudder trunk is below the deepest waterline two separate stuffing boxes are to be provided.

**iii)** **Materials.** The steel used for the rudder trunk is to be of weldable quality, with a carbon content not exceeding 0.23% on ladle analysis or a carbon equivalent (Ceq) not exceeding 0.41%. Plating materials for rudder trunks are in general not to be of lower grades than corresponding to class II as defined in 3-1-2/1.1 TABLE 1. Rudder trunks comprising of materials other than steel are to be specially considered.

**iv)** **Scantlings.** Where the rudder stock is arranged in a trunk in such a way that the trunk is stressed by forces due to rudder action, the scantlings of the trunk are to be such that the equivalent stress due to bending and shear does not exceed 0.35\( \sigma_F \), and the bending stress on welded rudder trunk is to be in compliance with the following formula:

\[ \sigma \leq \frac{80}{k} \text{N/mm}^2 \]
\[ \sigma \leq \frac{8.17}{k} \text{kgf/mm}^2 \]
\[ \sigma \leq 11.600/k \text{ psi} \]

where
\[ \sigma = \text{bending stress in the rudder trunk} \]
\[ k = K \text{ as defined in 3-2-8/1.3 for castings} \]
For calculation of bending stress, the span to be considered is the distance between the mid-height of the lower rudder stock bearing and the point where the trunk is clamped into the shell or the bottom of the skeg.

\[ \sigma_{F} = \frac{Q}{k} \]

For ordinary strength hull steel plate

\[ k = 1.0 \]

For higher strength steel plate

\[ k = Q \text{ as defined in 3-2-1/1.1.1} \]

\( k \) is not to be taken less than 0.7

\[ \sigma_{F} = \] specified minimum yield strength of the material used, in N/mm\(^2\) (kgf/mm\(^2\), psi)

Welding at the Connection to the Hull. The weld at the connection between the rudder trunk and the shell or the bottom of the skeg is to be full penetration and fillet shoulder is to be applied in way of the weld. The fillet shoulder radius \( r \), in mm (in.) (see 3-2-8/7.5 FIGURE 2) is to be as large as practicable and to comply with the following:

\[ r = 60 \text{ mm when } \sigma \geq 40/k \text{ N/mm}^2 \]
\[ r = 60 \text{ mm when } \sigma \geq 4.09/k \text{ kgf/mm}^2 \]
\[ r = 2.4 \text{ in. when } \sigma \geq 5800/k \text{ psi} \]
\[ r = 0.1S_{\ell}, \text{ without being less than 30 mm} \]
\[ \text{ when } \sigma < 40/k \text{ N/mm}^2 \]
\[ r = 0.1S_{\ell}, \text{ without being less than 30 mm} \]
\[ \text{ when } \sigma < 4.09/k \text{ kgf/mm}^2 \]
\[ r = 0.1S_{\ell}, \text{ without being less than 1.2 in.} \]
\[ \text{ when } \sigma < 2900/k \text{ psi} \]

where

\[ S_{\ell} = \] rudder stock diameter axis defined in 3-2-8/7.3
\[ \sigma = \] bending stress in the rudder trunk in N/mm\(^2\) (kgf/mm\(^2\), psi)
\[ k = \] material factor as defined in 3-2-8/7.5.iv

The radius may be obtained by grinding. If disk grinding is carried out, score marks are to be avoided in the direction of the weld. The radius is to be checked with a template for accuracy. Four profiles at least are to be checked. A report is to be submitted to the Surveyor.
7.7 Bending Moments

The bending moment on the rudder and rudder stock may be determined in accordance with Appendix 3-2-A1 or in accordance with the following equations:

7.7.1 Spade Rudders

\[ M_n = C_R \ell_n \text{ kN} - m(Lt f - ft) \]

\[ M_n = C_R \frac{A_1}{A} \ell_c \text{ kN} - m(Lt f - ft) \]

where

- \( M_n \) = bending moment at neck bearing.
- \( M_s \) = bending moment at section under consideration.
- \( \ell_n \) = distance from center of neck bearing to the centroid of rudder area, m (ft)
- \( \ell_c \) = distance from section under consideration to the centroid of rudder area, \( A_1 \), m (ft)
- \( A_1 \) = area below section under consideration, \( m^2 \) (ft²)

\( C_R \) and \( A \) are defined in 3-2-8/3.

7.7.2 Balanced Rudders with Shoepiece Support

The bending moment at the neck bearing may be taken as indicated below. Bending moments at other locations are to be determined by direct calculation and are to be submitted. See Appendix 3-2-A1 for guidance in calculating bending moments.

\[ M_n = N C_R \ell_b \text{ kN} - m(Lt f - ft) \]

where
\( M_n = \) bending moment at neck bearing
\( \ell_b = \) distance between center of neck bearing and center of shoepiece pintle bearing, m (ft)
\( N = \left[ \frac{0.5 + \frac{\alpha_1}{b}}{1 + \alpha_1 \left( 1 + \frac{\ell_u/b}{\ell_b} \right)^2} \right] \)
\( \alpha_1 = \frac{\ell_b^3 I_d}{\ell_s^3 I_b} \)
\( I_d = \) mean moment of inertia of shoepiece about the vertical axis, cm^4 (in^4)
\( \ell_s = \) distance between center of shoepiece pintle bearing and the effective support point of the shoepiece in the hull, m (ft)
\( I_b = \) mean moment of inertia of the rudder, cm^4 (in^4), considering a width of rudder plating twice the athwartship dimension of the rudder and excluding welded or bolted cover plates for access to pintles, inc.
\( \ell_u = \) distance between center of the neck bearing and the center of the rudder carrier bearing, m (ft)
\( I_u = \) mean moment of inertia of rudder stock, between neck bearing and rudder carrier bearing, cm^4, (in^4) CR is

\[ CR \] is as defined in 3-2-8/3.

9. **Flange Couplings**

9.1 **General**
Rudder flange couplings are to comply with the following requirements:

i) Couplings are to be supported by an ample body of metal worked out from the rudder stock.

ii) The smallest distance from the edge of the bolt holes to the edge of the flange is not to be less than two-thirds of the bolt diameter.

iii) Coupling bolts are to be fitted bolts.

iv) Suitable means are to be provided for locking the nuts in place.

In addition to the above, rudder flange couplings are to meet the type-specific requirements in 3-2-8/9.3 (horizontal couplings) or 3-2-8/9.5 (vertical couplings) as applicable.

9.3 **Horizontal Couplings**

9.3.1 **Coupling Bolts**
There are to be at least six coupling bolts in horizontal couplings, and the diameter, \( d_b \), of each bolt is not to be less than obtained by the following equation:

\[
 d_b = 0.62 \sqrt{\frac{d_s^2 K_b}{(nrK_s)}} \text{ mm (in.)}
\]

where

\( d_s = \) required rudder stock diameter, \( S \) (3-2-8/7.1) or \( S' \) (3-2-8/7.3) as applicable, in way of the coupling

\( n = \) total number of bolts in the horizontal coupling
9.3.2 Coupling Flange

Coupling flange thickness is not to be less than the greater of the following equations:

\[ t_f = \frac{d_{bt} \sqrt{K_f / K_b}}{K_b} \text{ mm (in.)} \]

\[ t_f = 0.9d_{bt} \text{ mm (in.)} \]

where

\[ d_{bt} = \text{calculated bolt diameter as per 3-2-8/9.3.1 based on a number of bolts not exceeding 8} \]

\[ K_f = \text{material factor for flange, as defined in 3-2-8/1.3} \]

\[ K_b = \text{material factor of bolts, as defined in 3-2-8/1.3} \]

9.3.3 Joint between Rudder Stock and Coupling Flange (1 July 2016)

The welded joint between the rudder stock and the flange is to be made in accordance with 3-2-8/9.3.3 FIGURE 3 or equivalent.

**FIGURE 3**

Welded Joint Between Rudder Stock and Coupling Flange (1 July 2016)

9.5 Vertical Couplings

9.5.1 Coupling Bolts (1 July 2016)

There are to be at least eight coupling bolts in vertical couplings and the diameter, \( d_b \), of each bolt is not to be less than obtained from the following equation:
\[ d_b = 0.81d_s \sqrt{K_b/(nK_s)} \text{ mm (in.)} \]

where

\[ n = \text{total number of bolts in the vertical coupling, which is not to be less than 8} \]

\[ d_s, K_b, K_s \text{ are as defined in 3-2-8/9.3.} \]

In addition, the first moment of area, \( m \), of the bolts about the center of the coupling is not to be less than given by the following equation:

\[ m = 0.00043 \, d_s^3 \text{ mm}^3 \text{ (in}^3) \]

where

\[ d_s = \text{diameter as defined in 3-2-8/9.3} \]

9.5.2 Coupling Flange

Coupling flange thickness, \( t_f \), is not to be less than \( d_b \), as defined in 3-2-8/9.5.1.

9.5.3 Joint between Rudder Stock and Coupling Flange (1 July 2016)

The welded joint between the rudder stock and the flange is to be made in accordance with 3-2-8/9.3.3 FIGURE 3 or equivalent.

11 Tapered Stock Couplings

11.1 Coupling Taper (1 July 2016)

Tapered stock couplings are to comply with the following general requirements in addition to type-specific requirements given in 3-2-8/11.3 or 3-2-8/11.5 as applicable:

\( i \)

Tapered stocks, as shown in 3-2-8/11 FIGURE 4, are to be effectively secured to the rudder casting by a nut on the end.

\( ii \)

The cone shapes are to fit exactly.

\( iii \)

Taper length (\( \ell \)) in the casting is generally not to be less than 1.5 times the stock diameter (\( d_o \)) as shown in 3-2-8/11 FIGURE 4.

\( iv \)

The taper on diameter (\( c \)) is to be 1/12 to 1/8 for keyed taper couplings and 1/20 to 1/12 for couplings with hydraulic mounting/dismounting arrangements, as shown in the following table.

\( v \)

Where mounting with an oil injection and hydraulic nut, the push-up oil pressure and the push-up length are to be specially considered upon submission of calculations.

\( vi \)

Means of effective sealing are to be provided to protect against sea water ingress.

<table>
<thead>
<tr>
<th>Type of Coupling Assembly</th>
<th>( c = \frac{d_o - d_u}{\ell} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Without hydraulic mounting/dismounting</td>
<td>( 1/12 \leq c \leq 1/8 )</td>
</tr>
<tr>
<td>With hydraulic mounting/dismounting</td>
<td>( 1/20 \leq c \leq 1/12 )</td>
</tr>
</tbody>
</table>
11.3 **Keyed Fitting (1 July 2019)**

Where the stock, it is to be fitted in accordance with the following:

1. The top of the keyway is to be located well below the top of the rudder.
2. Torsional strength of the key equivalent to that of the required upper stock is to be provided.
3. For the couplings between stock and rudder the shear area* of the key is not to be less than:

   \[
   a_s = \frac{17.55Q_F}{d k \sigma F} \text{ cm}^2
   \]

   \[
   a_s = \frac{21.06Q_F}{d k \sigma F} \text{ in}^2
   \]

   where

   \[Q_F = \text{design yield moment of rudder stock, in N-m (kgf-m, lbf-ft)}\]

   \[= 0.02664 \frac{d^3}{k} \text{ N} \cdot \text{m}\]

   \[= 0.002717 \frac{d^3}{k} \text{ kgf} \cdot \text{m}\]

   \[= 321.9838 \frac{d^3}{k} \text{ lbf} \cdot \text{ft}\]

   Where the actual rudder stock diameter \(d_{ta}\) is greater than the calculated diameter \(d_t\), the diameter \(d_{ta}\) is to be used. However, \(d_{ta}\) applied to the above formula need not be taken greater than 1.145 \(d_t\).
\[ d_t = \text{stock diameter, in mm (in.), according to 3-2-8/7.1} \]
\[ k = \text{material factor for stock as given in 3-2-8/1.3} \]
\[ d_k = \text{mean diameter of the conical part of the rudder stock, in mm (in.), at the key} \]
\[ \sigma_{F1} = \text{minimum yield stress of the key material, in N/mm}^2 (\text{kgf/mm}^2, \text{psi}) \]

The effective surface area of the key (without rounded edges) between key and rudder stock or cone coupling is not to be less than:

\[ a_k = \frac{5Q_F}{d_k\sigma_{F2}} \text{ cm}^2 \]
\[ a_k = \frac{6Q_F}{d_k\sigma_{F2}} \text{ in}^2 \]

where

\[ \sigma_{F2} = \text{minimum yield stress of the key, stock or coupling material, in N/mm}^2 (\text{kgf/mm}^2, \text{psi}), \text{ whichever is less.} \]

iv) In general, the key material is to be at least of equal strength to the keyway material. For keys of higher strength materials, shear and bearing areas of keys and keyways may be based on the respective material properties of the keys and the keyways, provided that compatibilities in mechanical properties of both components are fully considered. In no case, is the bearing stress of the key on the keyway to exceed 90% of the specified minimum yield strength of the keyway material.

v) Push up. It is to be proved that 50% of the design yield moment is solely transmitted by friction in the cone couplings. This can be done by calculating the required push-up pressure and push-up length according to 3-2-8/11.5.iv and 3-2-8/11.5.v for a torsional moment \( Q_k = 0.5Q_F \).

Notwithstanding the requirements in 3-2-8/11.5.ii and 3-2-8/11.5.iv, where a key is fitted to the coupling between stock and rudder and it is considered that the entire rudder torque is transmitted by the key at the couplings.

*Note: *The effective area is to be the gross area reduced by any area removed by saw cuts, set screw holes, chamfer, etc., and is to exclude the portion of the key in way of spooning of the key way.

11.5 Keyless Fitting (1 July 2019)

Hydraulic and shrink fit keyless couplings are to be fitted in accordance with the following:

i) Detailed preloading stress calculations and fitting instructions are to be submitted;

ii) Prior to applying hydraulic pressure, at least 75% of theoretical contact area of rudder stock and rudder bore is to be achieved in an evenly distributed manner;

iii) The upper edge of the upper main piece bore is to have a slight radius;

iv) Push-up Pressure. The push-up pressure is not to be less than the greater of the two following values:

\[ P_{req1} = \frac{2Q_F}{d_m^2\mu_0}10^3 \text{ N/mm}^2 (\text{kgf/mm}^2) \]
\[ P_{req1} = \frac{24Q_F}{d_m^2\mu_0} \text{ psi} \]
\[ P_{req2} = \frac{6M_b}{d_m^2}10^3 \text{ N/mm}^2 (\text{kgf/mm}^2) \]
\[ p_{\text{req}2} = \frac{72M_b}{d_m^2} \text{ psi} \]

where

\[ Q_F = \text{design yield moment of rudder stock, as defined in 3-2-8/11.3.iii} \]
\[ d_m = \text{mean cone diameter, in mm (in.)} \]
\[ \ell = \text{cone length, in mm (in.)} \]
\[ \mu_0 = \text{frictional coefficient, equal to 0.15} \]
\[ M_b = \text{bending moment in the cone coupling (e.g., in case of spade rudders), in N-m (kgf-m, lbf-ft)} \]

It has to be proved by the designer that the push-up pressure does not exceed the permissible surface pressure in the cone. The permissible surface pressure is to be determined by the following formula:

\[ p_{\text{perm}} = \frac{0.95Y_G(1 - a^2)}{\sqrt{3 + a^4}} - p_b \text{ N/mm}^2(\text{kgf/mm}^2, \text{psi}) \]

where

\[ p_b = \frac{3.5M_b}{d_m\ell^2} \times 10^3 \text{ N/mm}^2(\text{kgf/mm}^2) \]
\[ = \frac{42M_b}{d_m\ell^2} \text{ psi} \]
\[ Y_G = \text{specified minimum yield strength of the material of the gudgeon or stock, whichever is smaller, in N/mm}^2(\text{kgf/mm}^2, \text{psi}) \]
\[ \alpha = \frac{d_m}{d_a} \]
\[ d_m = \text{mean cone diameter, in mm (in.)} \]
\[ d_a = \text{outer diameter of the gudgeon, in mm (in.)} \]

The outer diameter of the gudgeon in mm (in.) shall not be less than 1.25d_0, with d_0 defined in 3-2-8/11 FIGURE 4.

v) **Push-up Length.** The push-up length \( \Delta\ell \), in mm (in.), \( \Delta\ell \) is to comply with the following formula:

\[ \Delta\ell_1 \leq \Delta\ell \leq \Delta\ell_2 \]

where

\[ \Delta\ell_1 = \frac{p_{\text{req}}d_m}{\ell(1 - a^2)} + \frac{0.8R_{tm}}{c} \text{mm (in.)} \]
\[ \Delta\ell_2 = \frac{p_{\text{perm}}d_m}{\ell(1 - a^2)} + \frac{0.8R_{tm}}{c} \text{mm (in.)} \]
\[ R_{tm} = \text{mean roughness, in mm (in.) taken equal to 0.01} \]
\[ c = \text{taper on diameter according to 3-2-8/11.1iv} \]
\[ Y_G = \text{specified minimum yield strength of the material of the gudgeon, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi) } \]

\[ E = \text{Young's modulus of the material of the gudgeon, in N/mm}^2 \text{ (kgf/mm}^2, \text{ psi) } \]

\[ Y_G, \alpha, \text{ and } d_m \text{ are as defined in 3-2-8/11.5.iv.} \]

Note: In case of hydraulic pressure connections the required push-up force \( P_e \) for the cone may be determined by the following formula:

\[ P_e = p_{req}d_m\pi\left(\frac{c}{2} + 0.02\right) \text{ N (kgf, psi) } \]

The value 0.02 is a reference for the friction coefficient using oil pressure. It varies and depends on the mechanical treatment and roughness of the details to be fixed. Where due to the fitting procedure a partial push-up effect caused by the rudder weight is given, this may be taken into account when fixing the required push-up length, subject to approval.

vi) Couplings with Special Arrangements for Mounting and Dismounting the Couplings. Where the stock diameter exceeds 200 mm (8 in.), the press fit is recommended to be effected by a hydraulic pressure connection. In such cases the cone is to be more slender, \( c \approx 1:12 \text{ to } \approx 1:20 \). In case of hydraulic pressure connections the nut is to be effectively secured against the rudder stock or the pintle. For the safe transmission of the torsional moment by the coupling between rudder stock and rudder body the push-up pressure and the push-up length are to be determined according to 3-2-8/11.5.iv and 3-2-8/11.5.v, respectively.

vii) The locking nut is to be fitted in accordance with 3-2-8/11.7.

11.7 Locking Nut

Dimensions of the securing nut, as shown in 3-2-8/9.3.3 FIGURE 3, are to be proportioned in accordance with the following and the nut is to be fitted with an effective locking device.

- Height \( h_n \geq 0.6d_g \)
- Outer diameter of nut \( d_n \geq 1.2d_u \) or \( 1.5d_g \), whichever is greater
- External thread diameter \( d_g \geq 0.65d_o \)

In the case of a hydraulic pressure secured nut, a securing device such as a securing flat bar is to be provided. Calculations proving the effectiveness of the securing device are to be submitted.

13 Pintles

13.1 General (1 July 2016)

Pintles are to have a conical attachment to the gudgeons with a taper on diameter of:

- 1/12 to 1/8 for keyed and other manually assembled pintles with locking nut.
- 1/20 to 1/12 for pintle mounted with oil injection and hydraulic nut.

13.3 Diameter (1 July 2019)

The diameter of the pintles is not to be less than obtained from the following equation.

\[ d_p = k_1\sqrt{BR_p} \text{ mm(in.)} \]

where
\[ k_1 = 11.1 \ (34.7, \ 1.38) \]
\[ B = \text{bearing force, in kN (tf, Ltf), from 3-2-8/13.5 but not to be taken less than } B_{\text{min}} \text{ as specified in 3-2-8/13.3} \]
\[ K_p = \text{material factor for the pintle, as defined in 3-2-8/1.3} \]

**TABLE 4**

**Minimum Bearing Force** \( B_{\text{min}} \) **(2009)**

<table>
<thead>
<tr>
<th>Pintle Type</th>
<th>( B_{\text{min}} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Conventional two pintle rudder</td>
<td>0.5 ( C_R )</td>

<tr>
<td>3-2-A1/7.1 FIGURE 3</td>
<td>lower pintle</td>
</tr>
<tr>
<td>3-2-A1/7.1 FIGURE 3</td>
<td>main pintle</td>
</tr>
<tr>
<td>3-2-13/5 FIGURE 3 of the Marine Vessel Rules</td>
<td>main pintle</td>
</tr>
<tr>
<td></td>
<td>upper pintle</td>
</tr>
</tbody>
</table>

* \( B_{\text{min}} = CR \) where \( \ell_a / \ell_p \geq 1 \)

\( \ell_a, \ell_p \) as described in 3-2-13/5 FIGURE 3 of the Marine Vessel Rules

For rudders on horns with two pintles, as shown in 3-2-8/3 FIGURE 1B, calculations are to include pintle bearing forces with the craft running ahead at the maximum continuous rated shaft rpm and at the lightest operating draft.

Threads and nuts are to be in accordance with 3-2-8/11.7.

The pintle and pintle boss are to comply with the following requirements:

1. The depth of the pintle boss is not to be less than \( d_p \).
2. The bearing length of the pintle is to be between 1.0 and 1.2 times the pintle diameter, where \( d_p \) is measured on the outside of the liner.
3. The bearing pressure is to be in accordance with 3-2-8/15.1.
4. The thickness of the pintle housing is not to be less than 25% of the pintle diameter.

Renewal limits are based upon pintle diameter without exceeding the following limits:

1. Spade type rudders: 6 mm.
2. Other rudders: 7.5 mm.

Special consideration is to be given to metal bearings and unique rudder types.

### 13.4 Push-up Pressure and Push-up Length (1 July 2019)

The required push-up pressure for pintles, in N/mm² (kgf/mm², psi), is to be determined by the following formula:

\[
p_{\text{req}} = \frac{0.4 B_1 d_o}{d_{\text{min}}^l} \ N/\text{mm}^2 \ (\text{kgf/mm}^2, \ \text{psi})
\]
where

\( B_1 = \) supporting force in the pintle, in N (kgf, lbf)

\( d_o = \) actual pintle diameter excluding the liner, in mm (in.)

\( d_m = \) mean cone diameter, in mm (in.)

\( \ell = \) cone length, in mm (in.)

The push up length is to be calculated similarly as in 3-2-8/11.5.v, using required push-up pressure and properties for the pintle.

### 13.5 Shear and Bearing Forces

The shear and bearing forces may be determined in accordance with Appendix 3-2-A1, or by the equations given below.

#### 13.5.1 Spade Rudder

Bearing force at rudder carrier:

\[
P_u = \frac{M_n}{\ell_u} \text{kN (tf, Ltf)}
\]

Bearing force at neck bearing:

\[
P_n = C_R + P_u \text{kN (tf, Ltf)}
\]

Shear force at neck bearing:

\[
F_n = C_R \text{kN (tf, Ltf)}
\]

where \( C_R \) is as defined in 3-2-8/3 and \( \ell_u \) is as defined in 3-2-8/7.7.2.

#### 13.5.2 Balanced Rudder with Shoepiece Support

Bearing force at rudder carrier:

\[
P_u = \frac{M_n}{\ell_u} \text{kN (tf, Ltf)}
\]

Bearing force at neck bearing:

\[
P_n = P_u \left(1 + \frac{\ell_u}{\ell_b}\right) + \frac{C_R \ell_r}{\ell_b^2} \text{kN (tf, Ltf)}
\]

where

\( \ell_b = \) distance between the center of neck bearing support and the center of shoepiece support, as shown in 3-2-A1/5.1 FIGURE 2

\( = \ell_p + \ell_r + \ell_\ell \)

\( \ell_p = \) distance between bottom of rudder blade and center of support of neck bearing

\( \ell_\ell = \) distance between top of rudder blade and center of support of neck bearing

Bearing force at shoepiece:

\[
P_p = C_R + P_u - P_n \text{ kN (tf, Ltf) but not less than } 0.5C_R
\]

Shear force at neck bearing:

\[
F_n = P_n - P_u \text{kN (tf, Ltf)}
\]

where \( C_R \) is as defined in 3-2-8/3.

### 15 Supporting and Anti-Lifting Arrangements

#### 15.1 Bearings

Bearing surfaces for rudder stocks, shafts and pintles are to meet the following requirements:
15.1.1 Bearing Surfaces  

i) The length/diameter ratio \( \frac{\ell_b}{d} \) of the bearing surface is not to be greater than 1.2*

ii) The projected area of the bearing surface \( A_b = d_\ell \ell_b \) is not to be less than \( A_{b\text{min}} \),

where

\[
\begin{align*}
  d_\ell &= \text{outer diameter of the liner, in mm (in.)} \\
  \ell_b &= \text{bearing length, in mm (in.)} \\
  A_{b\text{min}} &= k_1 \frac{P}{p_a} \text{mm}^2 \text{(in}^2) \\
  k_1 &= 1000 \text{ (2240)} \\
  P &= \text{bearing reaction force, in kN (tf, Ltf), as determined from 3-2-8/15.1.5 TABLE 5} \\
  p_a &= \text{allowable surface pressure, as indicated in 3-2-8/15.1.5 TABLE 6, depending on bearing material, in N/mm}^2 \text{ (kgf/mm}^2, \text{psi)}
\end{align*}
\]

* Request for bearing arrangement of length/diameter ratio greater than 1.2 is subject to special consideration provided that calculations are submitted to show acceptable clearance at both ends of the bearing.

15.1.2 Bearing Clearance  

i) The clearance for metal bearings is not to be less than \( \frac{d_i}{1000} + 1.0 \text{ mm (in.)} \) on the diameter, where \( d_i \) is the inner diameter of the bushing, in mm (in.).

ii) The clearance for non-metallic bearings is to be specially determined considering the material’s swelling and thermal expansion properties. This clearance in general is not to be taken less than 1.5 mm (0.06 in.) on diameter*.

* Request of clearance less than 1.5 mm (0.06 in.) for non-metallic bearings is subject to special considerations provided that documented evidence, such as manufacturer’s recommendation on acceptable clearance, expansion allowance and satisfactory service history with reduced clearances, are submitted for review.

For spade rudders with a rudder stock diameter of 400 mm (15.75 in.) or less, the clearances on the diameter are not to be less than given below:

<table>
<thead>
<tr>
<th>Stock Diameter, mm (in.)</th>
<th>Metallic Bushing, mm (in.)</th>
<th>Synthetic Bushing (^{(1)}), mm (in.)</th>
</tr>
</thead>
<tbody>
<tr>
<td>400 (15.75)</td>
<td>1.15 (0.045)</td>
<td>1.15 (0.045) + ( E^{(2)} )</td>
</tr>
<tr>
<td>300 (11.81)</td>
<td>0.85 (0.033)</td>
<td>0.85 (0.033) + ( E )</td>
</tr>
<tr>
<td>200 (7.87)</td>
<td>0.78 (0.031)</td>
<td>0.78 (0.031) + ( E )</td>
</tr>
<tr>
<td>100 (3.94)</td>
<td>0.75 (0.030)</td>
<td>0.75 (0.030) + ( E )</td>
</tr>
</tbody>
</table>

Notes:

1. The bushing manufacturer’s recommended running clearance may be used as an alternative to these clearances.

2. \( E \) = expansion allowance provided by bushing manufacturer, mm (in.).

15.1.3 Bearing Pressure  

Bearing pressure is to be accordance with 3-2-8/15.1.5 TABLE 6.
15.1.4 Bearing Material
Where stainless steel or wear-resistant steel is used for liners or bearings, the material properties including chemical composition of both components are to be submitted for review for an approved combination.

15.1.5 Liners and Bushes (1 July 2016)

i) Rudder Stock Bearings. Liners and bushes are to be fitted in way of bearings. The minimum thickness of liners and bushes is to be equal to:

\[ t_{\text{min}} = 8 \text{ mm (0.31 in.)} \]
for metallic materials and synthetic material

\[ t_{\text{min}} = 22 \text{ mm (0.87 in.)} \]
for lignum material

ii) Pintle Bearings

- The thickness of any liner or bush is neither to be less than:

\[ t = k_1 \sqrt{B} \text{ mm (in.)} \]

where

\[ B = \text{bearing force, in N (kgf, lbf)} \]
\[ k_1 = 0.01 (0.0313, 0.000830) \]

nor than the minimum thickness defined in 3-2-8/15.1.5.i.

- The bearing length \( L_p \) of the pintle is to be in accordance with 3-2-8/13.1.

### TABLE 5

</tbody>
</table>
Notes:
1 Indentation hardness test at 23°C (73.4°F) and with 50% moisture, according to a recognized standard. Synthetic bearing materials to be of approved type.
2 Higher values than given in the table may be taken if they are verified by tests, but in no case more than 10 N/mm² (1.02 kgf/mm², 1450 psi).
3 Stainless and wear-resistant steel in an approved combination with stock liner.

15.3 Rudder Carrier (1 July 2016)

i) The weight of the rudder assembly is to be supported by a rudder carrier mounted on the hull structure designed for that purpose.

ii) At least half of the rudder carrier’s holding-down bolts are to be fitted bolts. Alternative means of preventing horizontal movement of the rudder carrier may be considered.

iii) The bearing part is to be well lubricated by dripping oil, automatic grease feeding, or a similar method.

iv) Hull structures in way of the rudder carrier are to be suitably strengthened.

15.5 Anti Lifting Devices

Means are to be provided to prevent accidental unshipping or undue movement of the rudder which may cause damage to the steering gear. There are to be at least two bolts in the joint of the anti-lifting ring.

17 Double Plate Rudder

17.1 Strength (1 July 2017)

The section modulus and web area of the rudder mainpiece are to be such that the stresses indicated in the following Subparagraphs are not exceeded.

In calculating the section modulus of the rudder, the effective width of side plating is to be taken as not greater than twice the athwartship dimension of the rudder. Bolted cover plates on access openings to pintles are not to be considered effective in determining the section modulus of the rudder. In order for a cover plate to be considered effective, it is to be closed using a full penetration weld and confirmed suitable by non-destructive testing method. Generous radii are to be provided at abrupt changes in section where there are stress concentrations, including in way of openings and cover plates. When inspection windows are located in the panel below the rudder hub, the stress is to be as permitted in way of cutouts.

Moments, shear forces and reaction forces are to be as given in 3-2-8/7.7 and 3-2-8/13.5.

For spade rudders and rudders with horns, the section modulus at the bottom of the rudder is not to be less than one-third the required section modulus of the rudder at the top of the rudder or at the center of the lowest pintle.

Special attention is to be paid in design and construction of rudders with slender foil sections in the vicinity of their trailing edge (e.g., hollow foil sections, fishtail foil sections). Where the width of the rudder blade at the aftermost vertical diaphragm, \( w \), is equal or less than \( \frac{1}{6} \) of the trailing edge length measured between the diaphragm and the trailing edge, \( \ell \), finite element vibration analysis of the rudder blade is also to be submitted for review. See 3-2-8/17.1 FIGURE 5.
Spade rudders with an embedded rudder trunk are to have a trailing edge with dimensions that satisfy the following requirements:

1) For a rudder trailing edge having a monotonous transition to a rounded end with a finite thickness or diameter (see 3-2-8/17.1.i FIGURE 6), the vortex shedding frequency calculated using the equation given below is to be higher than 35 Hz.

\[ f_s = \frac{S_t U}{\beta_D D + \beta_T T} \]

where

- \( f_s \) = vortex shedding frequency, in Hz
- \( U \) = flow velocity, in m/s (ft/s), which is taken as craft’s design speed with craft running ahead at the maximum continuous rated shaft rpm and at the summer load waterline
- \( S_t \) = nominal Strouhal number
  - = 0.18
- \( \beta_D \) = 0.27
- \( C \) = minimal chord length of rudder cross section profile, in m (ft)
- \( D \) = nominal boundary layer thickness at trailing edge
  - = 0.01\( C \)
- \( \beta_T \) = 0.77
- \( T \) = thickness or diameter of rounded end, in m (ft)
For a rudder trailing edge with a flat insert plate (see 3-2-8/17.1.ii FIGURE 7), the insert plate thickness, \( t_0 \), is to be no larger than 1.5\( V_d \) in mm, where \( V_d \) is the design speed in ahead condition, in knots, as defined in 3-2-8/3.1. The extension beyond the weld to rudder plate, \( \ell \), is to satisfy the following 3-2-8/17.1.ii FIGURE 7 and with consideration of possible local vibratory bending of the insert plate.

**FIGURE 7 (1 July 2017)**

Alternatively, a vibration analysis is to be carried out to confirm that the natural frequency of the rudder is to be at least ±20% away from the vortex shedding frequency preferably determined using either a detailed numerical analysis method such as CFD or testing for ballast and full draft at 85% and 100% \( V_d \) as defined in 3-2-8/3.1.

17.1.1 **Clear of Rudder Recess Sections (1 July 2019)**

Allowable stresses for determining the rudder strength clear of rudder recess sections (cutouts) where 3-2-8/17.1.2 applies are as follows:

- **Bending stress**
  \[ \sigma_b = \frac{K_\sigma}{Q} \quad \text{N/mm}^2 \quad (\text{kgf/mm}^2, \text{psi}) \]

- **Shear stress**
  \[ t = \frac{K_t}{Q} \quad \text{N/mm}^2 \quad (\text{kgf/mm}^2, \text{psi}) \]

- **Equivalent stress**
  \[ \sigma_e = \sqrt{\sigma_b^2 + 3t^2} = \frac{K_e}{Q} \quad \text{N/mm}^2 \quad (\text{kgf/mm}^2, \text{psi}) \]

where

<table>

\( Q \) = as defined in 3-2-1/1.1.1

17.1.2 **In Way of Rudder Recess Sections (1 July 2019)**

Allowable stresses for determining the rudder strength in way of the recess sections (cutouts) for the rudder horn pintle on semi-spade rudders (see 3-2-8/17.1.2 FIGURE 8) are as follows:

- **Bending stress**
  \[ \sigma_b = \frac{K_\sigma}{Q} \quad \text{N/mm}^2 \quad (\text{kgf/mm}^2, \text{psi}) \]

- **Shear stress**
  \[ t = \frac{K_t}{Q} \quad \text{N/mm}^2 \quad (\text{kgf/mm}^2, \text{psi}) \]

- **Equivalent stress**
  \[ \sigma_e = \sqrt{\sigma_b^2 + 3t^2} = K_e \quad \text{N/mm}^2 \quad (\text{kgf/mm}^2, \text{psi}) \]
where

</table>

Note: The stresses in 3-2-8/17.1.2 apply equally to high tensile and ordinary steels.

FIGURE 8 (2009)

The mainpiece of the rudder is to be formed by the rudder side plating (but not more than the effective width indicated above) and vertical diaphragms extending the length of the rudder or the extension of the rudder stock or a combination of both.

17.3 Side, Top and Bottom Plating (1 July 2016)

The plating thickness is not to be less than obtained from the following equation:

$$ t = 0.0055s\beta\sqrt{k_1d + (k_2C_R/A) \times \sqrt{Q}} + k_3 \quad \text{mm(in.)} $$

where

- $k_1 = 1.0 (1.0, 0.305)$
- $k_2 = 0.1 (0.981, 10.7)$
- $k_3 = 2.5 (2.5, 0.1)$
- $d = \text{summer loadline draft of the craft, in m (ft)}$
\[ C_R = \text{rudder force according to 3-2-8/3, in kN (tf, Ltf)} \]
\[ A = \text{rudder area, in m}^2 \text{ (ft}^2) \]
\[ s = \text{smaller unsupported dimension of plating, in mm (in.)} \]
\[ b = \text{greater unsupported dimension of plating, in mm (in.)} \]
\[ \beta = \sqrt{1.1 - 0.5\left(\frac{s}{b}\right)^2}; \text{ maximum 1.0 for } \frac{b}{s} \geq 2.5 \]
\[ Q = \text{material factor for rudder plating, as defined in 3-2-1/1.1} \]

The thickness of the rudder side or bottom plating is to be at least 2 mm (0.08 in.) greater than that required by 3-2-3/1.3 with \( p \) obtained from 3-2-2/9.1, for which \( h \) is measured from the lower edge of the plate to the design load waterline in displacement mode.

The rudder side plating in way of the solid part is to be of increased thickness per 3-2-8/17.7.

### 17.5 Diaphragm Plates (2018)

Vertical and horizontal diaphragms are to be fitted within the rudder, effectively attached to each other and to the side plating. Vertical diaphragms are to be spaced approximately 1.5 times the spacing of horizontal diaphragms. Openings are in general not to be more than 0.5 times the depth of the web.

The thickness of diaphragm plates is not to be less than 70% of the required rudder side plate thickness or 8 mm (0.31 in.), whichever is greater. Openings in diaphragms are to have generous radii and the effects of openings are to be considered in the strength assessment as required in 3-2-8/17.1.

The diaphragm plating in way of the solid part is to be of increased thickness for vertical and horizontal diaphragm plates per 3-2-8/17.7.

### 17.7 Connections of Rudder Blade Structure with Solid Parts (1 July 2019)

Solid parts in forged or cast steel, which house the rudder stock or the pintle, are to be provided with protrusions, except where not required as indicated below.

These protrusions are not required when the diaphragm plate thickness is less than:

- 10 mm (0.375 in.) for diaphragm plates welded to the solid part on which the lower pintle of a semispade rudder is housed and for vertical diaphragm plates welded to the solid part of the rudder stock coupling of spade rudders.
- 20 mm (0.75 in.) for other diaphragm plates.

The solid parts are in general to be connected to the rudder structure by means of two horizontal diaphragm plates and two vertical diaphragm plates.

Minimum section modulus of the connection with the rudder stock housing.

The section modulus of the cross-section of the structure of the rudder blade formed by vertical diaphragm plates and rudder plating, which is connected with the solid part where the rudder stock is housed is to be not less than:

\[ w_s = c_s S \left( \frac{H_E - H_X}{H_E} \right)^2 \frac{Q}{K_s} 10^{-4} \text{ cm}^3 \]
\[ w_s = c_s S \left( \frac{H_E - H_X}{H_E} \right)^2 \frac{Q}{K_s} 10^{-1} \text{ in}^3 \]

where
\( c_s = \) coefficient, to be taken equal to:

\[ = 1.0 \quad \text{if there is no opening in the rudder plating or if such openings are closed by a full penetration welded plate} \]

\[ = 1.5 \quad \text{if there is an opening in the considered cross-section of the rudder} \]

\( S_\ell = \) rudder stock diameter, in mm (in.)

\( H_E = \) vertical distance between the lower edge of the rudder blade and the upper edge of the solid part, in m (ft)

\( H_X = \) vertical distance between the considered cross-section and the upper edge of the solid part as indicated in 3-2-8/17.7 FIGURE 9, in m (ft)

\( Q = \) material factor for the rudder blade plating as given in 3-2-8/17.1

\( K_s = \) material factor for the rudder stock as given in 3-2-8/1.3

The actual section modulus of the cross-section of the structure of the rudder blade is to be calculated with respect to the symmetrical axis of the rudder.

The breadth of the rudder plating to be considered for the calculation of section modulus is to be not greater than:

\[ b = s_v + 2H_x/3 \quad \text{m(ft)} \]

where

\( s_v = \) spacing between the two vertical diaphragm, in m (ft) (see 3-2-8/9)

Where openings for access to the rudder stock nut are not closed by a full penetration welded plate, they are to be deducted.
The thickness of the horizontal diaphragm plates connected to the solid parts, in mm (in.), as well as that of the rudder blade plating between these diaphragms, is to be not less than the greater of the following values:

\[ t_H = 1.2t \text{ mm(in.)} \]

\[ t_H = 0.045d_S^2 / s_H \text{ mm(in.)} \]

where

- \( t \) = defined in 3-2-8/17.3
- \( d_S \) = diameter, in mm (in.), to be taken equal to:
  - \( S_F \) as per 3-2-8/7.3, for the solid part housing the rudder stock
  - \( d_p \) as per 3-2-8/13.1, for the solid part housing the pintle
- \( s_H \) = spacing between the two horizontal diaphragm plates, in mm (in.)

The increased thickness of the horizontal diaphragms is to extend fore and aft of the solid part at least to the next vertical diaphragm.
The thickness of the vertical diaphragm plates welded to the solid part where the rudder stock is housed as well as the thickness of the rudder side plating under this solid part is to be not less than the values obtained, in mm (in.), from 3-2-8/17.7 TABLE 7.

The increased thickness of vertical diaphragm plates is to extend below the solid piece at least to the next horizontal diaphragm.

**TABLE 7**

**Thickness of Side Plating and Vertical Diaphragm Plates (1 July 2016)**

<td>2.0t</td>
</tr>
</tbody>
</table>

\( t = \) thickness of the rudder plating, in mm (in.), as defined in 3-2-8/17.3

**17.9 Welding and Design Details (1 July 2016)**

- **i)** Slot-welding is to be limited as far as possible. Slot welding is not to be used in areas with large in-plane stresses transversely to the slots or in way of cut-out areas of semi-spade rudders.
- **ii)** When slot welding is applied, the length of slots is to be minimum 75 mm (3 in.) with breadth of 2\( t \), where \( t \) is the rudder plate thickness, in mm (in.). The distance between ends of slots is not to be more than 125 mm (5 in.). The slots are to be fillet welded around the edges and filled with a suitable compound (e.g., epoxy putty). Slots are not to be filled with weld.
- **iii)** Grove welds with structural backing/backing bar (continuous type slot weld) may be used for double-plate rudder welding. In that case, the root gap is to be between 6 to 10 mm (0.25 to 0.375 in.) and the bevel angle is to be at least 15°.
- **iv)** In way of the rudder horn recess of semi-spade rudders the radii in the rudder plating are not to be less than 5 times the plate thickness, but in no case less than 100 mm (4 in.). Welding in side plate are to be avoided in or at the end of the radii. Edges of side plate and weld adjacent to radii are to be ground smooth.
- **v)** Welds between plates and heavy pieces (solid parts in forged or cast steel or very thick plating) are to be made as full penetration welds. In way of highly stressed areas (e.g., cut-out of semi-spade rudder and upper part of spade rudder), cast or welding on ribs is to be arranged. Two sided full penetration welding is normally to be arranged. Where back welding is impossible welding is to be performed against ceramic backing bars or equivalent. Steel backing bars may be used and are to be continuously welded on one side to the heavy piece.

**17.11 Watertightness (1 July 2016)**

The rudder is to be watertight and is to be tested in accordance with Section 3-7-1.

**19 Single Plate Rudders**

**19.1 Mainpiece Diameter**

The mainpiece diameter is calculated according to 3-2-8/7.3. For spade rudders, the lower third may be tapered down to 0.75 times stock diameter at the bottom of the rudder.
19.3 **Blade Thickness**

The blade thickness is not to be less than obtained from the following equation:

\[
t_b = 0.0015sV_R + 2.5\text{ mm}
\]

\[
t_b = 0.0015sV_R + 0.1\text{ in.}
\]

where

\[
s = \text{spacing of stiffening arms, in mm (in.), not to exceed 1000 mm (39 in.)}
\]

\[
V_R = \text{speed, as defined in 3-2-8/3.1}
\]

19.5 **Arms**

The thickness of the arms is not to be less than the blade thickness obtained in 3-2-8/19.3. The section modulus of each set of arms about the axis of the rudder stock is not to be less than obtained from the following equation:

\[
SM = 0.0005sC_1^2V^2\text{ cm}^3
\]

\[
SM = 0.0000719sC_1^2V^2\text{ in}^3
\]

where

\[
C_1 = \text{horizontal distance from the aft edge of the rudder to the centerline of the rudder stock, in m (ft)}
\]

\[
Q = \text{as defined in 3-2-1/1.1.1}
\]

\[
s, V_R \text{ are defined in 3-2-8/19.3}
\]

21 **Shelled Rudder Blades**

Rudder blades that are constructed out of cast resilient polymers or filled FRP shells are to have a solid metallic core that complies with the requirements for single plate rudders, see 3-2-8/19.
PART 3

CHAPTER 2  Hull Structures and Arrangements

SECTION 9  Protection of Deck Openings

1  General

All openings in decks are to be framed to provide efficient support and attachment for the ends of the deck beams. The proposed arrangement and details for all hatchways are to be submitted for approval.

3  Position of Deck Openings

For the purpose of these Rules, two positions of deck openings are defined as follows:

Position 1  Upon exposed main and raised quarter decks, and upon exposed superstructure decks situated forward of a point located a quarter of the craft length from the forward perpendicular.

Position 2  Upon exposed superstructure decks situated abaft a quarter of the craft length from the forward perpendicular.

5  Hatchway Coamings, Companionway Sills and Access Sills

5.1  Coaming and Sill Heights

The heights above deck of the coamings, the sills of companionways and access openings, are to be not less than given in 3-2-9/5.1 TABLE 1. Where hatch covers are substantially constructed and made tight by means of gaskets and clamping devices, these heights may be reduced, or the coamings omitted entirely, provided that the safety of the craft is not thereby impaired in any sea conditions. Sealing arrangements are to be weathertight if coaming is fitted, and watertight for flush covers.

<td>300 mm (12 in.)</td>
</tr>
</tbody>
</table>

Note: For craft with \( L < 24 \) m, the coaming/sill height should be as indicated above.
7 Enclosed Superstructures

To be considered enclosed, superstructures are to meet the following requirements. Superstructures with openings which do not fully comply with these requirements are to be considered as open superstructures. See also 3-2-11/3.7.

7.1 Closing Appliances

All openings in the bulkheads of enclosed superstructures are to be provided with efficient means of closing, so that in any sea conditions water will not penetrate the craft. Opening and closing appliances are to be framed and stiffened so that the whole structure, when closed, is equivalent to the unpierced bulkhead.

Doors for access openings into enclosed superstructures are to be of steel or other approved material, permanently and strongly attached to the bulkhead. The doors are to be provided with gaskets and clamping devices, or other equivalent arrangements, permanently attached to the bulkhead or to the doors themselves, and the doors are to be so arranged that they can be operated from both sides of the bulkhead. The construction of the doors is to be as required in 3-2-5/1.13.

Portlights and windows in the end bulkheads of enclosed superstructures are to be of substantial construction and provided with efficient inside deadlights, as required in 3-2-11/5.

The location and means of the closing appliances for windows are to be in accordance with 3-2-11/7.

7.3 Sills of Access Openings

Except as otherwise provided in these Rules, the height of the sills of access openings in bulkheads at the ends of enclosed superstructures is to be at least 380 mm (15 in.) above the deck. See 3-2-9/5.1 TABLE 1 for required sill heights.

7.5 Means of Access

Superstructures are not to be regarded as enclosed unless access is provided for the crew to reach machinery and other working spaces inside these superstructures by alternate means which are available at all times when bulkhead openings are closed.

9 Hatchways Closed by Covers of Steel and Fitted with Gaskets and Clamping Devices

9.1 Strength of Covers

The maximum allowable stress and deflection under design load, \( w \), and the minimum top plate thickness are as follows:

- Maximum allowable stress: \( 0.235\sigma_u \)
- Maximum allowable deflection: \( 0.0028s \)
- Top plate thickness: \( 0.01s \), but not less than 6.0 mm (0.24 in.)

*Position 1*

\[
\begin{align*}
w &= 0.097L + 7.45 \quad \text{kN/m}^2 \\
W &= 0.0099L + 0.76 \quad \text{tf/m}^2 \\
W &= 0.61L + 158.0 \quad \text{lbf/ft}^2
\end{align*}
\]

*Position 2*
\[ w = 0.0709L + 5.65 \quad \text{kN/m}^2 \]
\[ w = 0.00725L + 0.576 \quad \text{tf/m}^2 \]
\[ w = 0.450L + 118.5 \quad \text{lbf/ft}^2 \]

where

\[ w = \text{design load, in kN/m}^2 (\text{tf/m}^2, \text{lbf/ft}^2) \]
\[ L = \text{length of craft, in m (ft), as defined in Section 3-1-1, but is not to be taken less than 24 m (79 ft).} \]
\[ s = \text{stiffener spacing, in mm (in.)} \]
\[ \sigma_u = \text{minimum ultimate tensile strength, in N/mm}^2 (\text{kgf/mm}^2, \text{psi}) \]

9.3 **Means for Securing Weathertightness**

The means for securing and maintaining weathertightness is to be such that the tightness can be maintained in any sea condition. The covers are to be hose tested in position under a water pressure of at least 2.1 bar (2.1 kgf/cm², 30 psi) at the time of installation.

9.5 **Flush Hatch Covers**

Where flush hatch covers are fitted on the freeboard deck within the forward one-fourth length, and the craft is operating with low freeboard (e.g., assigned a freeboard less than Type-B under the International Convention on Load Lines 1966), the assumed loads on flush hatch covers are to be increased 15% over that indicated in 3-2-9/9.1.

11 **Hatchways Closed by Portable Covers in Lower Decks or within Fully Enclosed Superstructures**

11.1 **General**

The following scantlings are intended for conventional type covers. Those for covers of special types are to be specially considered.

11.3 **Steel Covers**

The thickness of the plating for steel covers is not to be less than required for lower decks as obtained from 3-2-3/1. A stiffening bar is to be fitted around the edges as required to provide the necessary rigidity to permit the covers being handled without deformation. The effective depth of the framework is normally to be not less than 4% of its unsupported length. The stiffeners, in association with the plating to which they are attached, are to have section modulus, \( SM \), as determined by the following equation:

\[ SM = 7.8hs\ell^2 \quad \text{cm}^3 \]
\[ SM = 0.0041hs\ell^2 \quad \text{in}^3 \]

where

\[ h = \text{tween-deck height, in m (ft)} \]
\[ s = \text{spacing of the stiffeners, in m (ft)} \]
\[ \ell = \text{length of the stiffener, in m (ft)} \]
11.5 **Wheel Loading**
Where provision is to be made for the operation and stowage of vehicles having rubber tires, the thickness of the hatch cover plating is to be in accordance with 3-2-3/1.9.

13 **Hatchways Closed by Covers of Materials Other Than Steel**
Hatch covers constructed of materials other than steel will be specially considered.

15 **Small Hatches on the Exposed Fore Deck**

15.1 **Application**
This subsection is applicable to craft with length $L$ (as defined in 3-1-1/3) not less than 80 meters (263 feet).

The requirements of this subsection apply to all small hatches [opening normally 2.5 square meters (27 ft$^2$) or less] located on the exposed fore deck within the forward $0.25L$, where the deck in way of the hatch is less than $0.1L$ or 22 m (72.2 ft) above the summer load line, whichever is less.

Hatches designed for emergency escape need not comply with 3-2-9/15.5.i, 3-2-9/15.5.ii the third paragraph of 3-2-9/15.7 and 3-2-9/15.9.

15.3 **Strength**
For small rectangular steel hatch covers, the plate thickness, stiffener arrangement and scantlings are to be in accordance with 3-2-9/15.9 TABLE 2 and 3-2-9/15.9 FIGURE 1. Stiffeners, where fitted, are to be aligned with the metal-to-metal contact points required in 3-2-9/15.7. See also 3-2-9/15.9 FIGURE 1. Primary stiffeners are to be continuous. All stiffeners are to be welded to the inner edge stiffener, see 3-2-9/15.9 FIGURE 2.

The upper edge of the hatchway coaming is to be suitably reinforced by a horizontal section, normally not more than 170 to 190 mm (6.9 to 7.5 in.) from the upper edge of the coaming.

For small hatch covers of circular or similar shape, the cover plate thickness and reinforcement is to provide strength and stiffness equivalent to the requirements for small rectangular hatches.

For small hatch covers constructed of materials other than steel, the required scantlings are to provide strength and stiffness equivalent to 235 N/mm$^2$ (24 kgf/mm$^2$, 34 psi) yield strength steel.

15.5 **Primary Securing Devices**
The primary securing devices are to be such that their hatch covers can be secured in place and made weather-tight by means of a mechanism employing any one of the following methods:

$i)$ Butterfly nuts tightening onto forks (clamps), or

$ii)$ Quick acting cleats, or

$iii)$ A central locking device.

Dogs (twist tightening handles) with wedges are not acceptable.

15.7 **Requirements for Primary Securing**
The hatch cover is to be fitted with a gasket of elastic material. This is to be designed to allow a metal-to-metal contact at a designed compression and to prevent over compression of the gasket by green sea forces that may cause the securing devices to be loosened or dislodged. The metal-to-metal contacts are to be arranged close to each securing device in accordance with 3-2-9/15.9 FIGURE 1, and of sufficient capacity to withstand the bearing force.
The primary securing method is to be designed and manufactured such that the designed compression pressure is achieved by one person without the need of any tools.

For a primary securing method using butterfly nuts, the forks (clamps) are to be of robust design. They are to be designed to minimize the risk of butterfly nuts being dislodged while in use; by means of curving the forks upward and a raised surface on the free end, or a similar method. The plate thickness of unstiffened steel forks is not to be less than 16 mm. An example arrangement is shown in FIGURE 2.

For small hatch covers located on the exposed deck forward of the fore-most cargo hatch, the hinges are to be fitted such that the predominant direction of green sea will cause the cover to close, which means that the hinges are normally to be located on the fore edge.

On small hatches located between the main hatches, for example between Nos. 1 and 2, the hinges are to be placed on the fore edge or outboard edge, whichever is practicable for protection from green water in beam sea and bow quartering conditions.

15.9 Secondary Devices

Small hatches on the fore deck are to be fitted with an independent secondary securing device e.g., by means of a sliding bolt, a hasp or a backing bar of slack fit, which is capable of keeping the hatch cover in place, even in the event that the primary securing device became loosened or dislodged. It is to be fitted on the side opposite to the hatch cover hinges.

---

17 **Hatchways within Open Superstructures**

Hatchways within open superstructures are to be considered as exposed.

19 **Hatchways within Deckhouses**

Hatchways within deckhouses are to have coamings and closing arrangements as required in relation to the protection afforded by the deckhouse from the standpoint of its construction and the means provided for the closing of all openings into the house.
21 Machinery Casings

21.1 Arrangement

Machinery-space openings in Position 1 or 2 are to be framed and efficiently enclosed by casings of ample strength, and wherever practicable, those in main decks are to be within superstructures or deckhouses. Casings are to be of material similar to that of the surrounding structure. Openings in exposed casings are to be fitted with doors complying with the requirements of 3-2-9/7.1; the sills are to be in accordance with 3-2-9/5.1 for companionways. Other openings in such casings are to be fitted with equivalent covers, permanently attached. Stiffeners are to be spaced at not more than 760 mm (30 in.)

21.3 Scantlings

The scantlings of exposed casings are to be similar to those obtained for superstructures and deckhouses in accordance with the applicable requirements of Sections 3-2-2, 3-2-3 and 3-2-4.

The scantlings of casings within enclosed superstructures or deckhouses will be specially considered.

23 Miscellaneous Openings in Freeboard and Superstructure Decks

23.1 Manholes and Scuttles

Manholes and flush scuttles in Position 1 or 2 within superstructures other than enclosed superstructures are to be closed by substantial covers capable of being made watertight. Unless secured by closely spaced bolts, the covers are to be permanently attached.

23.3 Other Openings

Openings in freeboard decks other than hatchways, machinery-space openings, manholes and flush scuttles are to be protected by an enclosed superstructure, or by a deckhouse or companionway of equivalent strength and weathertightness. Any such opening in an exposed superstructure deck or in the top of a deckhouse on the main deck which gives access to a space below the main deck or a space within an enclosed superstructure is to be protected by an efficient deckhouse or companionway. Doorways in such deckhouses or companionways are to be fitted with doors complying with the requirements given in 3-2-9/7.1.

23.5 Escape Openings (1 July 2012)

i) The closing appliances of escape openings are to be of a type that is operable from each side.

ii) The maximum force needed to open the hatch cover is not to exceed 150 N (15.3 kgf, 33.7 lbf).

iii) The use of a spring equalizing, counterbalance or other suitable device on the hinge side to reduce the force needed for opening is acceptable.

23.7 Chain Pipe Opening (1 July 2012)

For craft with length $L$ (as defined in 3-1-1/3) greater than 24 meters (79 feet), chain pipes through which anchor cables are led are to be provided with permanently attached closing appliances to minimize ingress of water. A canvas cover with appropriate lashing arrangement will be acceptable* for this purpose. Cement and wire mesh arrangement is not permitted.

The arrangement on craft that are not subject to the International Convention on Load Lines or its Protocol may be specially considered.

Notes:

* Examples of acceptable arrangements are such as:

i) Steel plates with cutouts to accommodate chain links or
ii Canvas hoods with a lashing arrangement that maintains the cover in the secured position.
CHAPTER 2  Hull Structures and Arrangements

SECTION 10  Protection of Shell Openings

1  Cargo, Gangway, or Fueling Ports

1.1  Construction
Cargo, gangway, or fueling ports in the sides of craft are to be strongly constructed and capable of being made thoroughly watertight. Where frames are cut in way of such ports, web frames are to be fitted on the sides of the openings, and suitable arrangements are to be provided for the support of the beams over the openings. Thick shell plates or doublers are to be fitted as required to compensate for the openings. The corners of the openings are to be well rounded. Waterway angles and scuppers are to be provided on the decks in way of ports in cargo spaces below the freeboard deck or in cargo spaces within enclosed superstructures to prevent the spread of any leakage water over the decks.

Indicators showing whether the ports in the side shell below the freeboard or superstructure deck are secured closed or open are to be provided on the navigation bridge.

1.3  Location
The lower edges of cargo, gangway, or fueling-port openings are not to be below a line parallel to the main deck at side having as its lowest point the designed load waterline or upper edge of the uppermost load line.

3  Bow Doors, Inner Doors, Side Shell Doors and Stern Doors

3.1  General
Where steel bow doors of the visor or side-opening type are fitted leading to complete or long forward enclosed superstructure, bow doors and inner doors are to meet the requirements of this section. Hull supporting structure in way of the bow doors is to be able to withstand the loads imposed by the bow doors securing and supporting devices without exceeding the allowable stresses for those devices, both given in this section. Special consideration will be given to bow doors constructed of materials other than steel.

3.3  Arrangement
3.3.1  General
As far as practicable, bow doors and inner doors are to be arranged so as to preclude the possibility of the bow door causing structural damage to the inner door or to the collision bulkhead in the case of damage to or detachment of the bow door.

3.3.2  Bow Doors
Bow doors are to be situated above the main deck except that where a watertight recess fitted for arrangement of ramps or other related mechanical devices is located forward of the collision bulkhead and above the deepest waterline, the bow doors may be situated above the recess.
3.3.3 Inner Doors
An inner door is to be fitted in the extension of the collision bulkhead required by 3-2-5/1.3. A vehicle ramp made watertight and conforming to 3-2-5/1.3 in the closed position may be accepted for this purpose.

3.3.4 Side Shell and Stern Doors
Stern doors for passenger craft are to be situated above the freeboard deck. Stern doors for ro-ro cargo craft and all side shell doors need not be situated above the freeboard deck.

5 Securing, Locking and Supporting of Doors

5.1 Definitions
5.1.1 Securing Device
A device used to keep the door closed by preventing it from rotating about its hinges or its pivoted attachments to the craft.

5.1.2 Supporting Device
A device used to transmit external or internal loads from the door to a securing device and from the securing device to the craft’s structure, or a device other than a securing device, such as a hinge, stopper or other fixed device, that transmits loads from the door to the craft’s structure.

5.1.3 Locking Device
A device that locks a securing device in the closed position.

7 Securing and Supporting Devices

7.1 General
Securing and supporting devices are to be arranged in accordance with this subsection, and are to have scantlings as required by 3-2-10/13.9, 3-2-10/15.5 or 3-2-10/17.9, as appropriate.

7.3 Bow Doors
Means are to be provided to prevent lateral or vertical movement of the bow doors when closed. Means are also to be provided for mechanically fixing the door in the open position.

Means of securing and supporting the door are to maintain equivalent strength and stiffness of the adjacent structure.

7.3.1 Clearance and Packing
The maximum design clearance between the door and securing/supporting devices is not to exceed 3 mm (0.12 in.). Where packing is fitted, it is to be of a comparatively soft type and the supporting forces are to be carried by the steel structure only.

7.3.2 Visor Door Arrangement.
The pivot arrangement is to be such that the visor is self-closing under external loads. The closing moment, $M_y$, as defined in 3-2-10/19.5.1 is not to be less than $M_{yo}$ as given by the following equation:

$$M_{yo} = W_c + 0.1\sqrt{a^2 + b^2F_x^2 + F_z^2}$$

where $W, a, b, c, F_x$ and $F_z$ are as defined in 3-2-10/19.
In addition, the arrangement of the door is to be such that the reaction forces of pin or wedge supports at the base of the door does not act in the forward direction when the door is loaded in accordance with 3-2-10/19.5.4.

7.5 Side Shell and Stern Doors
Means are to be provided to prevent lateral or vertical movement of the side shell or stern doors when closed. Means are also to be provided for mechanically fixing the doors in the open position.

The means of securing and supporting the doors are to have strength and stiffness equivalent to the adjacent structure.

Clearance and packing for side shell and stern doors are to be in accordance with 3-2-10/7.3.1.

9 Securing and Locking Arrangement

9.1 General
Securing devices are to be provided with a mechanical locking arrangement (self-locking or separate arrangement), or are to be of the gravity type.

9.3 Operation
Securing devices are to be simple to operate and readily accessible. The opening and closing systems as well as the securing and locking devices are to be interlocked in such a way that they can only operate in the proper sequence.

9.3.1 Hydraulic Securing Devices
Where hydraulic securing devices are applied, the system is to be mechanically lockable in the closed position. In the event of a loss of hydraulic fluid, the securing devices are to remain locked.

The hydraulic system for securing and locking devices is to be isolated from other hydraulic circuits when in the closed position.

9.3.2 Remote Control
Where bow doors and inner doors give access to a vehicle deck, an arrangement for remote control from a position above the freeboard deck is to be provided allowing closing and opening of the doors and associated securing and locking of the securing and locking devices for every door. The operating panels for operation of doors are to be accessible to authorized persons only.

A notice plate giving instructions to the effect that all securing devices are to be closed and locked before leaving harbor is to be placed at each operating panel and is to be supplemented by warning indicator lights as indicated in 3-2-10/9.5.1.

9.5 Indication/Monitoring

9.5.1 Indicators
The indicator system is to be designed on the fail safe principle and in accordance with the following:

9.5.1(a) Location and Type.
Separate indicator lights are to be provided on the navigation bridge to show that the bow door and inner door are closed and that their locking devices are properly positioned.

The indication panel on the navigation bridge is to be equipped with a mode selection function “harbor/sea voyage”, arranged so that an audible and visible alarm is given if in the sea voyage condition, the bow door or inner door is not closed, or any of the securing devices is not in the correct position.
Indication of the open/closed position of every door and every securing and locking device is to be provided at the operating panels.

9.5.1(b) Indicator lights.
Indicator lights are to be designed so that they cannot be manually turned off. The indication panel is to be provided with a lamp test function.

9.5.1(c) Power Supply.
The power supply for the indicator system is to be independent of the power supply for operating and closing the doors.

9.5.1(d) Protection of Sensors.
Sensors are to be protected from water, ice formation and mechanical damage.

9.5.2 Water Leakage Protection
A drainage system is to be arranged in the area between the bow door and ramp and in the area between the ramp and inner door where fitted. The system is to be equipped with an audible alarm function to the navigation bridge for water level in these areas exceeding 0.5 m (1.6 ft) above the car deck level.

A water leakage detection system with audible alarm and television surveillance are to be arranged to provide an indication to the navigation bridge and to the engine control room of leakage through the inner door.

9.5.3 Door Surveillance
Between the bow door and the inner door a television surveillance system is to be fitted with a monitor on the navigation bridge and in the engine control room. The system is to monitor the position of doors and a sufficient number of their securing devices.

11 Tightness

11.1 Bow Doors
Bow doors are to be so fitted as to provide tightness consistent with operational conditions and to give effective protection to the inner doors.

11.3 Inner Doors
Inner doors forming part of the extension of the collision bulkhead are to be weathertight over the full height of the cargo space and arranged with fixed sealing supports on the aft side of the doors.

11.5 Side Shell and Stern Doors
Side shell doors and stern doors are to be so fitted as to provide watertightness.

13 Bow Door Scantlings

13.1 General
Bow doors are to be framed and stiffened so that the whole structure is equivalent to the unpierced bulkhead when closed.

13.3 Primary Structure
Scantlings of primary members are to be designed so that the allowable stresses indicated in 3-2-10/25.1 are not exceeded when the structure is subjected to the design loads indicated in 3-2-10/19.1. Unless the
ends of the primary members are effectively fixed-ended, the member is to be considered simply supported.

### 13.5 Secondary Stiffeners

Secondary stiffeners are to be supported by primary members constituting the main stiffening of the door. The section modulus, $S_M$, of secondary stiffeners is to be as required by 3-2-4/1.3. In addition, stiffener webs are to have a net sectional area not less than that obtained from the following equation:

$$A = \frac{VQ}{10 \text{ cm}^2} \quad (A = \frac{VQ}{6.5 \text{ in}^2})$$

where

- $V$ = shear force, in kN (tf, Ltf), in the stiffener calculated using the uniformly distributed external pressure $P_{eb}$ given in 3-2-10/19.1
- $Q$ = as defined in 3-2-1/1.1.1

### 13.7 Plating

The thickness of bow door plating is to be not less than that required for side shell plating at the same location.

### 13.9 Securing and Supporting Devices

Scantlings of securing and supporting devices are to be designed so that the allowable stresses indicated in 3-2-10/25.1 are not exceeded when the structure is subjected to the design loads indicated in 3-2-10/19.3. All load transmitting elements in the design load path from the door through securing and supporting devices into the craft structure, including welded connections, are to meet the strength standards required for securing and supporting devices. Where fitted, threaded bolts are not to carry support forces, and the maximum tensile stress in way of the threads is not to exceed the allowable stress given in 3-2-10/25.5.

In determining the required scantlings, the door is to be assumed to be a rigid body. Only those active supporting and securing devices having an effective stiffness in the relevant direction are to be included and considered when calculating the reaction forces on the devices. Small or flexible devices such as cleats intended to provide load compression of the packing material are not to be included in the calculations.

#### 13.9.1 Bearing Pressure

The bearing pressure on steel to steel bearings is to be calculated by dividing the design force by the projected bearing area, and is not to exceed the allowable stress given in 3-2-10/25.3.

#### 13.9.2 Redundancy

In addition to the above requirements, the arrangement of the securing and supporting devices is to be designed with redundancy such that in the event of failure of any single securing or supporting device, the stresses in the remaining devices do not exceed the allowable stresses indicated in 3-2-10/25.1 by more than 20% under the above loads.

#### 13.9.3 Visor Door Securing and Supporting Devices

Securing and supporting devices, excluding the hinges, are to be capable of resisting the vertical design force given in 3-2-10/19.5.3 without stresses exceeding the allowable stresses in 3-2-10/25.1.

Two securing devices are to be provided at the lower part of the door, each capable of providing the full reaction force required to prevent opening of the door without stresses exceeding the allowable stresses indicated in 3-2-10/25.1. The opening moment, $M_o$, to be balanced by this force is as given in 3-2-10/19.5.2.
13.9.4 Side-opening Door Thrust Bearing
A thrust bearing is to be provided in way of girder ends at the closing of the two doors, and is to prevent one door from shifting towards the other one under the effect of unsymmetrical pressure. Securing devices are to be fitted to secure sections thrust bearing to one another.

13.11 Visor Door Lifting Arms and Supports
Where visor type bow doors are fitted, calculations are to be submitted verifying that lifting arms and their connections to the door and craft structure are adequate to withstand the static and dynamic forces applied during the lifting and lowering operations under a wind pressure of at least 1.5 kN/m$^2$ (0.15 tf/m$^2$, 0.014 Ltf/ft$^2$).

15 Inner Door Scantlings

15.1 General
Scantlings of inner doors are to meet the requirements of this Subsection. In addition, where inner doors are used as vehicle ramps, scantlings are not to be less than required for vehicle decks.

15.3 Primary Structure
Scantlings of primary members are to be designed so that the allowable stresses indicated in 3-2-10/25.1 are not exceeded when the structure is subjected to the design loads indicated in 3-2-10/21.1.

15.5 Securing and Supporting Devices
Scantlings of securing and supporting devices are to be designed so that the allowable stresses indicated in 3-2-10/25.1 are not exceeded when the structure is subjected to the design loads indicated in 3-2-10/21. Where fitted, threaded bolts are not to carry support forces, and the maximum tensile stress in way of the threads is not to exceed the allowable stress given in 3-2-10/25.5.

The bearing pressure on steel to steel bearings is to be calculated by dividing the design force by the projected bearing area, and is not to exceed the allowable stress given in 3-2-10/25.3.

17 Side Shell Door and Stern Door Scantlings

17.1 General
Scantlings of side shell doors or stern doors are to meet the requirements of this subsection. The doors are to be framed and stiffened so that the whole structure is equivalent to the intact side or stern structure when closed. In addition, where the doors are used as vehicle ramps, scantlings are not to be less than required for vehicle decks in Section 3-2-3 and Section 3-2-4.

17.3 Primary Structure
Scantlings of primary members are to be designed so that the allowable stresses indicated in 3-2-10/25.1 are not exceeded when the structure is subjected to the design loads indicated in 3-2-10/23. The primary members are to be considered simply supported at their support points unless the end connections are effectively restrained.

17.5 Secondary Stiffeners
Secondary stiffeners are to be supported by primary members constituting the main stiffening of the door. The section modulus, $SM$, of secondary stiffeners is to be not less than required by Section 3-2-4 for frames in the same location. In addition, the net sectional area of stiffener webs is to be in accordance with 3-2-10/13.5, using the external pressure, $p_e$, given in 3-2-10/23.
17.7 **Plating**

The thickness of side or stern door plating is to be not less than that required for side shell plating at the same location.

17.9 **Securing and Supporting Devices**

Scantlings of securing and supporting devices are to be designed so that the allowable stresses indicated in 3-2-10/25.1 are not exceeded when the structure is subjected to the design loads indicated in 3-2-10/23. All load-transmitting elements in the design load path from the door through securing and supporting devices into the craft structure, including welded connections, are to meet the strength standards required for securing and supporting devices. Where fitted, threaded bolts are not to carry support forces, and the maximum tensile stress in way of the threads is not to exceed the allowable stress given in 3-2-10/25.5.

In determining the required scantlings, the door is to be assumed to be a rigid body. Only those active supporting and securing devices having an effective stiffness in the relevant direction are to be included and considered when calculating the reaction forces on the devices. Small or flexible devices such as cleats intended to provide compression load on the packing material are not to be included in the calculations.

17.9.1 **Bearing Pressure**

The bearing pressure on steel to steel bearings is to be calculated by dividing the design force by the projected bearing area, and is not to exceed the allowable stress given in 3-2-10/25.3.

17.9.2 **Redundancy**

In addition to the above requirements, the arrangement of the securing and supporting devices is to be designed with redundancy such that in the event of a failure of any single securing or supporting device, the stresses in the remaining devices do not exceed the allowable stresses indicated in 3-2-10/25.1 by more than 20% under the above loads.

19 **Bow Door Design Loads**

19.1 **External Pressure**

The design external pressure, \( P_{eb} \), is to be taken as indicated by the following equation.

\[
P_{eb} = nc(0.22 + 0.15\tan\beta)(0.4V_d\sin\alpha + 0.6\sqrt{Ltf})^2 \text{kN/m}^2(\text{tf/m}^2, \text{Ltf/ft}^2)
\]

where

\[
\begin{align*}
n &= 2.75 (0.280, 0.0256) \\
c &= 0.0125L \text{ for craft having } L < 80 \text{ m (260 ft)} \\
  &= 1.0 \text{ for other craft} \\
L &= \text{length of craft as defined in 3-1-1/3, in m (ft)} \\
\beta &= \text{flare angle at the point to be considered, defined as the angle between a vertical line and the tangent to the side shell plating measured in a vertical plane normal to the horizontal tangent to the shell plating. See 3-2-10/19.1 FIGURE 1} \\
\alpha &= \text{entry angle at the point to be considered, defined as the angle between a longitudinal line parallel to the centerline and the tangent to the shell plating in a horizontal plane. See 3-2-10/19.1 FIGURE 1.} \\
k &= 1.0 (1.0, 0.305) \\
V_d &= \text{craft design speed as defined in 3-2-8/3.1}
\end{align*}
\]
19.3 **External Forces**

The design external forces considered in determining scantlings of securing and supporting devices of bow doors are not to be taken less than those given by the following equations:

\[
F_x = P_{em} A_x
\]

\[
F_y = P_{em} A_y
\]

\[
F_z = P_{em} A_z
\]

where

- \(F_x\) = design external force in the longitudinal direction, in kN (tf, Ltf)
- \(F_y\) = design external force in the horizontal direction, in kN (tf, Ltf)
- \(F_z\) = design external force in the vertical direction, in kN (tf, Ltf)
- \(A_x\) = area, in m\(^2\) (ft\(^2\)), of the transverse vertical projection of the door between the levels of the bottom of the door and the upper deck or between the bottom of the door and the top of the door, whichever is less.
- \(A_y\) = area, in m\(^2\) (ft\(^2\)), of the longitudinal vertical projection of the door between the levels of the bottom of the door and the upper deck or between the bottom of the door and the top of the door, whichever is less.
\[ A_z = \text{area, in } \text{m}^2 (\text{ft}^2), \text{ of the horizontal projection of the door between the levels of the bottom of the door and the upper deck or between the bottom of the door and the top of the door, whichever is less.} \]

\[ P_{em} = \text{bow door pressure, } P_{eb}, \text{ determined using } \alpha_m \text{ and } \beta_m \text{ in place of } \alpha \text{ and } \beta. \]

\[ \beta_m = \text{flare angle measured at a point on the bow door } \ell / 2 \text{ aft of the stem line on a plane } h / 2 \text{ above the bottom of the door, as shown in 3-2-10/19.3 FIGURE 2.} \]

\[ \alpha_m = \text{entry angle measured at the same point as } \beta_m. \text{ See 3-2-10/19.3 FIGURE 2.} \]

\[ h = \text{height, in m (ft), of the door between the levels of the bottom of the door and the upper deck or between the bottom of the door and the top of the door, whichever is less.} \]

\[ \ell = \text{length, in m (ft), of the door at a height of } h / 2 \text{ above the bottom of the door.} \]

**FIGURE 2**

**Definition of \( \alpha_m \) and \( \beta_m \)**

19.5 **Visor Door Forces, Moments and Load Cases**

19.5.1 **Closing Moment**

For visor doors, the closing moment, \( M_y \), is to be taken as indicated by the following equation:

\[ M_y = F_z a + W_c - F_z b \quad \text{kN} \quad \text{m (tf - m, Ltf - ft)} \]

where
\( W = \) weight of the visor door, in kN (tf, Ltf)

\( a = \) vertical distance, in m (ft), from the visor pivot to the centroid of the transverse vertical projected area of the visor door. See 3-2-10/19.5.1 FIGURE 3.

\( b = \) horizontal distance, in m (ft), from visor pivot to the centroid of the horizontal projected area of the visor door. See 3-2-10/19.5.1 FIGURE 3.

\( c = \) horizontal distance, in m (ft), from the visor pivot to the center of gravity of the visor. See 3-2-10/19.5.1 FIGURE 3.

\( F_x \) and \( F_z \) are as defined in 3-2-10/19.3.

**FIGURE 3**

Visor Type Bow Door

19.5.2 Opening Moment

The opening moment, \( M_o \), is to be taken as indicated by the following equation:
\[ M_0 = Wd + 5A_xa \quad \text{kN} - \text{m} \]
\[ \text{where} \]
\[ d = \text{vertical distance, in m (ft), from the hinge axis to the center of gravity of the door} \]
\[ W, A_x \text{ and } a \text{ are as indicated above.} \]

19.5.3 **Vertical Design Force**

The vertical design force is to be taken as \( F_z - W \), where \( F_z \) is as defined in 3-2-10/19.3 and \( W \) is as defined in 3-2-10/19.5.1.

19.5.4 **Combined Load Case 1**

The visor doors are to be evaluated under a load of \( F_x, F_y, F_z \) and \( W \) acting simultaneously with \( F_x \) and \( F_z \) acting at the centroid of their respective projected areas.

19.5.5 **Combined Load Case 2**

The visor doors are to be evaluated under a load of \( 0.7F_y \) acting on each side separately together with \( 0.7F_x, 0.7F_y \) and \( W, F_x, F_y \) and \( F_z \) are to be taken as acting at the centroid of their respective projected areas.

19.7 **Side-Opening Door Load Cases**

19.7.1 **Combined Load Case 1**

Side opening doors are to be evaluated under a load of \( F_x, F_y, F_z \) and \( W \) acting simultaneously with \( F_x, F_y \) and \( F_z \) acting at the centroid of their respective projected areas.

19.7.2 **Combined Load Case 2**

Side opening doors are to be evaluated under a load of \( 0.7F_x, 0.7F_y \) and \( W \) acting on both doors simultaneously and \( 0.7F_y \) acting on each door separately.

21 **Inner Door Design Loads**

21.1 **External Pressure**

The design external pressure is to be taken as the greater of \( P_{ei} \) or \( P_h \) as given by the following equations:

\[ P_{ei} = 0.45L_1 \quad \text{kN/m}^2 \left( 0.046L_1, 0.00128L_1 \quad \text{tf/m}^2, 0.029L_1 \quad \text{Ltf/ft}^2 \right) \]

\[ P_h = 10h \quad \text{kN/m}^2 \left( 1.0h, 0.029h \quad \text{tf/m}^2, 0.23 \quad \text{Ltf/ft}^2 \right) \]

\[ \text{where} \]
\[ L_1 = \text{as defined in 3-1-1/3.} \]
\[ h = \text{the distance, in m (ft), from the load point to the top of the cargo space.} \]

21.3 **Internal Pressure**

The design internal pressure, \( P_i \), is to be taken as not less than \( 25 \text{kN/m}^2 (2.5 \text{tf/m}^2, 0.23 \text{Ltf/ft}^2) \).
23 Side Shell and Stern Doors

23.1 Design Forces for Primary Members

The design force, in kN (tf, Ltf), for primary members is to be the greater of the following:

External force: \( F_e = A \ p_e \)

Internal force: \( F_i = F_o + W \)

23.3 Design Forces for Securing or Supporting Devices of Doors Opening Inwards

The design force, in kN (tf, Ltf), for securing or supporting devices of doors opening inwards is to be the greater of the following:

External force: \( F_e = A \ p_e + F_p \)

Internal force: \( F_i = F_o + W \)

23.5 Design Forces for Securing or Supporting Devices of Doors Opening Outwards (2016)

The design force, in kN (tf, Ltf), for securing or supporting devices of doors opening outwards is to be the greater of the following:

External force: \( F_e = A \ p_e \)

Internal force: \( F_i = F_o + W + F_p \)

where

\( A = \) area, in \( \text{m}^2 \) (ft\(^2\)), of the door opening

\( W = \) weight of the door, in kN (tf, Ltf)

\( F_p = \) total packing force, in kN (tf, Ltf). Packing line pressure is normally not to be taken less than 5.0 N/mm (0.51 kg/mm, 28.6 lbf/in).

\( F_o = \) the greater of \( F_c \) and \( k A \), in kN (tf, Ltf)

\( k = 5 \) (0.51, 0.047)

\( F_c = \) accidental force, in kN (tf, Ltf), due to loose cargo, etc., to be uniformly distributed over the area \( A \) and not to be taken less than 300 kN (30.6 tf, 30.1 Ltf). For small doors such as bunker doors and pilot doors, the value of \( F_c \) may be appropriately reduced. However, the value of \( F_c \) may be taken as zero provided an additional structure such as an inner ramp is fitted which is capable of protecting the door from accidental forces due to loose cargoes.

\( p_e = \) external design pressure, in kN/m\(^2\) (tf/ft\(^2\)), determined at the center of gravity of the door opening and not taken less than:

\[ p_e = k_1 \quad \text{for} \quad Z_G \geq d \]

\[ p_e = k_1 (d - Z_G) + k_1 \quad Z_G \geq d \]

Moreover, for craft fitted with bow doors, \( p_e \) for stern doors is not to be taken less than:

\[ p_e = nc \left( 0.8 + 0.6 (k_3 d)^{0.5} \right)^2 \]
For craft fitted with bow doors and operating in restricted service (see 1-2-2/7), the value of $p_e$ for stern doors will be specially considered.

\[
k_1 = 25.0 \quad (2.55, 0.233)
\]

\[
k_2 = 10.0 \quad (1.02, 0.0284)
\]

\[
d = \text{draft, in m (ft), as defined in 3-1-1/9}
\]

\[
Z_G = \text{height of the center of area of the door, in m (ft), above the baseline.}
\]

\[
n = 0.605 \quad (0.0616, 0.00563)
\]

\[
k_3 = 1.0 \quad (1.0, 0.305)
\]

\[
c = 0.0125L \quad \text{for } L < 80 \text{ m (262 ft)}
\]

\[
c = 1 \quad \text{for } L \geq 80 \text{ m (262 ft)}
\]

\[
L = \text{length of craft, in m (ft), as defined in 3-1-1/3, but need not be taken as greater than 200 m (656 ft).}
\]

### 25 Allowable Stresses

#### 25.1 Primary Structure and Securing and Supporting Devices

The following stresses are not to be exceeded under the loads indicated above:

Shear Stress:

\[
\tau = \frac{80}{Q} \quad \text{N/mm}^2 \quad (8.2/Q \quad \text{kgf/mm}^2, 11600/Q \quad \text{psi})
\]

Bending Stress:

\[
\sigma = \frac{120}{Q} \quad \text{N/mm}^2 \quad (12.2/Q \quad \text{kgf/mm}^2, 17400/Q \quad \text{psi})
\]

Equivalent Stress:

\[
\sigma_e = \frac{150}{Q} \quad \text{N/mm}^2 \quad (15.3/Q \quad \text{kgf/mm}^2, 21770/Q \quad \text{psi})
\]

where $Q$ is defined in 3-2-1/1.1.1.

#### 25.3 Steel Securing and Supporting Devices Bearing Stress

For steel to steel bearings in securing and supporting devices, the nominal bearing pressure is not to exceed $0.8\sigma_f$, where $\sigma_f$ is the yield stress of the bearing material.

#### 25.5 Tensile Stress on Threaded Bolts

The tensile stress in threaded bolts is not to exceed $125/Q \quad \text{N/mm}^2$ ($12.7/Q \quad \text{kgf/mm}^2$, $18,000/Q \quad \text{psi}$).

### 27 Operating and Maintenance Manual

The following information is to be submitted for review:

#### 27.1 Manual

An operating and maintenance manual for the bow door and inner door is to be provided on board and is to contain at least the following:

- Main particulars and design drawings
- Service conditions (e.g., service area)
- Restrictions, acceptable clearances for supports
- Maintenance and function testing
- Register of inspections and repairs
27.3 Operating Procedures

Documented operating procedures for closing and securing the bow door and inner door are to be kept on board and posted at an appropriate location.
CHAPTER 2 Hull Structures and Arrangements

SECTION 11 Bulwarks, Rails, Ports, Portlights, Windows, Ventilators, Tank Vents and Overflows

1 Bulwarks and Guard Rails

Bulwarks or guard rails or a combination of both, are in general to be provided on periphery of exposed decks, and on exposed tops of superstructures and deckhouses.

Where the flag administration has specific requirements for bulwarks and guardrails they may be accepted provided they are not less effective.

For vessels less than 24 meters (79 ft) in length, may be specially considered.

1.1 Location and Heights

Bulwarks or guardrails are also to be provided on the exposed side of any platform surface that is greater than 600 mm (24 in.) or higher above the adjacent surface.

The height of bulwarks and guard rails on exposed freeboard and superstructure decks, at the boundary of first tier deckhouses and at the ends of superstructures is to be at least 1 m (39.5 in.). Where this height would interfere with the normal service or operation of a craft, a lesser height may be approved if adequate protection is provided. Where approval of a lesser height is requested, justifying information is to be submitted, such as arrangements provided to prevent personnel going over the guard rails or bulwarks.

1.3 Strength of Bulwarks

Bulwarks are to be of ample strength for their height and location, suitably stiffened at the top, and if necessary at the bottom, and supported by efficient stays or brackets.

Stays or brackets on the main weather deck are to be spaced not more than 1.83 m (6.0 ft).

Openings in bulwarks are to be smooth-edged, with well-rounded corners.

1.5 Guard Rails

1.5.1

Fixed, removable or hinged stanchions are to be fitted at approximately 1.5 m (5 ft) apart. Removable or hinged stanchions are to be capable of being locked in the upright position.

1.5.2 (2017)

At least every third stanchion is to be supported by a bracket or stay. Dimensions and arrangement of stanchion and stays are to be as shown in 3-2-11/1.5.2.v FIGURE 1. Where this arrangement would interfere with the safe traffic of persons on board, the following alternative arrangements of stanchions may be acceptable:

i) At least every third stanchion is to be of increased breadth, \( kb_s = 2 \cdot 9b_s \) at the attachment of stanchion to the deck, or,

ii) At least every second stanchion is to be of increased breadth, \( kb_s = 2 \cdot 4b_s \) at the attachment of stanchion to the deck, or,
Every stanchion is to be of increased breadth, \( kb_s = 1.9 b_s \) at the attachment of stanchion to the deck.

where, \( b_s \) is not to be taken as less than 60 mm (2.36 in.) (see 3-2-11/1.5.2.v FIGURE 2).

The thickness of the flat bar stanchions is not to be less than 15 mm (0.59 in.).

For any of the above arrangements \( i), ii) \) or \( iii) \), the following details are to be complied with:

\( iv) \) Flat steel stanchion required by \( i), ii) \) or \( iii) \) above is to be aligned with supporting member below the deck unless the deck plating thickness exceeds 20 mm (0.79 in.) and welded to deck with double continuous fillet weld with minimum leg size of 7.0 mm (0.28 in.) or as specified by the design standard.

\( v) \) The underdeck supporting member of the stanchion is to be a minimum of 100 × 12 mm (4.0 × 0.5 in.) flat bar welded to deck by double continuous fillet weld.

**FIGURE 1**
Guardrail Stanchion

\[* = 20 \text{ mm} \text{ solid round bar or } 26.9 \text{ mm} \text{ outside diameter pipe with } 2.3 \text{ mm minimum wall thickness (or pipes having an equivalent section modulus) } \]

\[** \text{ Top Rail } = 42.4 \text{ mm} \text{ outside diameter pipe with } 2.6 \text{ mm minimum wall thickness (or pipes having an equivalent section modulus)} \]

Standard stanchion, rail, and stay sizes.
(Stay to be provided at every third stanchion)
1.5.3

The clear opening below the lowest course is not to exceed 230 mm (9 in.). Where a foot-stop is installed at the deck level, the clear opening below the lowest course may be measured from the top of the foot-stop. The clear distances between the lowest and the middle courses, as well as the middle and the upper courses are not to exceed 380 mm (15 in.).

The distance between the lower rail and the top of the sheerstrake is not to exceed 230 mm (9 in.).

1.5.4

For vessels with rounded gunwales, stanchions are to be placed on the flat of the deck.

1.7 Guard Rail Scantling Correction

When aluminum guard rails are used, calculate an equivalent section modulus to the standard shown in 3-2-11/1.5.2.v FIGURE 1, using the below formula.

\[ SM_{al} = 0.9Q_0SM_s \]

where

\[ SM_{al} = \] minimum section modulus of aluminum guardrail

\[ SM_s = \] offered section modulus of guardrail as shown in 3-2-11/1.5.2.v FIGURE 1
The material factor, \( Q \), is obtained from the following equation:

\[
Q = 0.9 + \left( \frac{120}{Y_{al}} \right) \quad \text{SI Units}
\]

\[
Q = 0.9 + \left( \frac{12}{Y_{al}} \right) \quad \text{MKS Units}
\]

\[
Q = 0.9 + \left( \frac{17000}{Y_{al}} \right) \quad \text{U.S. Units}
\]

but is not to be taken as less than \( Q_0 \) below.

The material factor, \( Q_0 \), is obtained from the following equation:

\[
Q_0 = \frac{635}{(\sigma_y + \sigma_u)} \quad \text{SI Units}
\]

\[
Q_0 = \frac{65}{(\sigma_y + \sigma_u)} \quad \text{MKS Units}
\]

\[
Q_0 = \frac{92000}{(\sigma_y + \sigma_u)} \quad \text{U.S. Units}
\]

Where \( Y_{al} \) = minimum yield strength of the welded aluminum alloy under consideration at 2% offset in a 254 mm (10 in.) gauge length, in N/mm\(^2\) (kgf/mm\(^2\), psi), in accordance with the requirements of the table below.

\( \sigma_u \) = minimum ultimate strength of the welded aluminum alloy under consideration, in N/mm\(^2\) (kgf/mm\(^2\), psi), in accordance with the table below.

\( \sigma_y \) = minimum yield strength of the welded aluminum alloy under consideration, in N/mm\(^2\) (kgf/mm\(^2\), psi), in accordance with the table below.

1.9 Life Lines

Life lines, where fitted, are to be a minimum of 9.5 mm (0.375 in.) in diameter, 7 \( \times \) 19 construction, and made of stainless steel wire rope. They are to have a stainless steel turnbuckle at one end and a stainless steel screw pin shackle at the other.

3 Freeing Ports

3.1 Basic Area for Craft More Than 24 meters (79 feet) in Length

Where bulwarks on freeboard decks form wells, ample provision is to be made for rapidly freeing the decks of water and for draining them. The minimum freeing-port area on each side of the craft for each well 20 m (66 ft.) or less in length is to be obtained from the following equation:

\[
A = 0.7 + 0.035\ell \quad \text{m}^2
\]

\[
A = 7.6 + 0.115\ell \quad \text{ft}^2
\]

Where the bulwark length exceeds 20 m (66 ft):

\[
A = 0.07\ell \quad \text{m}^2
\]

\[
A = 0.23\ell \quad \text{ft}^2
\]

where
A = freeing-port area in m² (ft²)
ℓ = bulwark length, in m (ft), but need not exceed 0.7L.

The minimum area for each well on superstructure decks is to be one half of the area obtained from the above equations.

If a bulwark is more than 1.2 m (3.9 ft) in height, the freeing-port area is to be increased by 0.004 m² per meter (0.04 ft² per foot) of length of well for each 0.1 m (1 ft) difference in height. If a bulwark is less than 0.9 m (3 ft) in height, the freeing-port area may be decreased by the same ratio. Where sheer is less than standard, the percentage is to be obtained by interpolation.

3.3 Basic Area for Craft Less Than 24 meters (79 feet) in Length
Freeing ports may comply with the requirements of a recognized standard acceptable to ABS in lieu of the requirements stated in 3-2-11/3.1. Examples of acceptable standards are given below:

- ABYC, Section H-4 Cockpits and Scuppers

3.5 Trunks, Deckhouses and Hatchway Coamings
Where a craft is fitted with a trunk on the freeboard deck, and open rails are not fitted in way of the trunk for at least one-half its length, or where continuous or substantially continuous hatchway side coamings are fitted or long deckhouse exist between detached superstructures, the minimum area of freeing-port openings is to be obtained from the following table:

<table>
<thead>
<tr>
<th>Breadth of Trunk, Deckhouse or Hatchway in Relation to Breadth of Craft</th>
<th>Area of Freeing Ports in Relation to Total Area of Bulwarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>40% or less</td>
<td>20%</td>
</tr>
<tr>
<td>75% or more</td>
<td>10%</td>
</tr>
</tbody>
</table>

The area of freeing ports at intermediate breadths is to be obtained by linear interpolation.

3.7 Superstructure Decks
Where bulwarks on superstructure decks form wells, the bulwarks are to comply with 3-2-11/3.1 except that the minimum freeing-port area on each side of the craft for each well is to be one-half of the area obtained in 3-2-11/3.1 and 3-2-11/3.3.

3.9 Open Superstructures
In craft having superstructures that are open at either end or both ends, adequate provisions for freeing the spaces within such superstructures are to be provided; the arrangements will be subject to special approval.

3.11 Details of Freeing Ports
The lower edges of the freeing ports are to be as near the deck as practicable. Two-thirds of the required freeing-port area is to be provided in the half of the well nearest the lowest point of the sheer curve. Freeing-port openings are to be protected by rails or bars in such a manner that the maximum clear vertical or horizontal space is 230 mm (9 in.). Where shutters are fitted, ample clearance is to be provided to prevent them from jamming. Hinges are to have pins and bearings of corrosion resistant material and in general, the hinges are to be located at the top of the shutter. If the shutters are equipped with securing appliances, the appliances are to be of approved construction.
5 Portlights

5.1 Location
No portlight is to be fitted in a position with its sill below a line drawn parallel to the freeboard deck at side and having its lowest point less than 0.025\(B\) above the maximum load waterline or 500 mm (19.5 in.), whichever is greater. In addition, portlights are not to be fitted in spaces which are used for the carriage of cargo.

5.3 Construction
Portlights fitted below the main weather deck or in superstructure and house side plating are to be of substantial construction and provided with steel, aluminum or other approved material inside deadlights, permanently attached and arranged to be capable of being closed and secured watertight. Except in way of the machinery space, portlights may be of the hinged opening type, with hinge pins of noncorrosive material. Where vessels are subject to damaged stability requirements of 3-3-1/3.3, portlights found to be situated below a final damage equilibrium waterline are to be of the non-opening type. Portlight frames are to be of steel or other approved material and are to be attached to the hull by through bolts or equivalent. Lower edges of portlights are not to be below a line parallel to the main weather deck at side having its lowest point at a distance above the design waterline either 2.5% of the craft breadth or 500 mm (19.5 in.) whichever is greater.

For craft limited in service range and weather conditions and not receiving a Load Line Certificate, consideration will be given to the omission of deadlights depending on the type and thickness of the portlight.

The thickness of portlights of tempered or toughened monolithic safety glass is to be not less than given in 3-2-11/5.5 TABLE 1. Consideration will also be given to laminated glass, acrylic and polycarbonate glazing materials based upon equivalent flexural strength and stiffness. See 3-2-11/7.1.3 TABLE 3 for glazing mechanical properties.

In addition to the above, where the craft is assigned a load line in accordance with the International Convention on Load Lines, 1966 (as amended), portlights and deadlights are to meet the requirements of Regulation 23 of the Convention.

5.5 Testing
All portlights are to be hose tested in position under a water pressure of at least 2 bar (2 kgf/cm\(^2\), 30 lb/in\(^2\))

The flexural strength of the glass is to be verified by compliance with the proof load in ISO 614.

</table>

Note: $k$ is to be taken from 3-2-11/7.1.3 TABLE 2; $s$ is the short panel dimension and $\ell$ is the long window dimension

7 Windows

7.1 Construction

Windows are defined as being rectangular openings generally, or oval, openings with an area exceeding 0.16 m$^2$(1.72 ft$^2$).

Windows to spaces within enclosed superstructure and deckhouses are to be fitted with strong steel, aluminum or other approved material, storm shutters. Windows are not to be fitted below the freeboard deck. Windows are not to be fitted in the first tier end bulkheads or sides of enclosed superstructures. Windows are not to be fitted in first tier deckhouses considered buoyant in the stability calculations or protecting openings leading below. Window frames are to be of steel or other approved material and are to be attached by through bolts or equivalent.

Windows on the second tier above the freeboard deck may not require deadlights depending upon the arrangement of the craft. Window frames are to be metal or other approval material, and effectively secured to the adjacent structure. Windows are to have a minimum of a $\frac{1}{4}”$ radius at all corners. The glazing is to be set into the frames in a suitable, approved packing or compound. Special consideration to be given to angled house fronts.

For externally fitted storm covers an arrangement for safe and easy access is to be provided.

For craft limited in service range and weather conditions and not receiving a Load Line Certificate, consideration will be given to the omission of deadlights depending on the location, type and thickness of the windows.

In addition to the above, where the craft is assigned a load line in accordance with the International Convention on Load Lines, 1966 (as amended), windows and storm shutters are to meet the requirements of Regulation 23 of the Convention.

The thickness of the window is not to be less than that obtained from 3-2-11/7.1.1, 3-2-11/7.1.2 or 3-2-11/7.1.3 below, whichever is greater.

7.1.1

$$t = s \left( \frac{pk}{10000} \right) \text{ mm}$$

$$t = s \left( \frac{pk}{sa} \right) \text{ in}.$$  

7.1.2

* Special considerations will be made with regards to design, manufacture and testing of glass specimens.

7.3 Testing

All windows are to be hose tested in position under a water pressure of at least 2 bar (2 kgf/cm², 30 lb/in²)
The flexural strength of the glass is to be verified by compliance with the proof load in ISO 614.

9 Ventilators, Tank Vents and Overflows

9.1 General
Ventilators are to comply with the requirements of 3-2-11/9.3. Tank vents and overflows are to comply with the requirements in 3-2-11/9.5. In addition, for those located on the fore deck of craft with length \( L \) (as defined in 3-1-1/3) not less than 80 meters (263 feet), the requirements given in 3-2-11/9.7 are to be complied with.

9.3 Ventilators
9.3.1 Coaming Construction (1 July 2016)
Ventilators on exposed freeboard decks, superstructure decks, or deckhouses are to have coamings of steel or equivalent material. Coaming plate thicknesses for steel are to be obtained from the following equation:

\[
t = 0.01d + 5.5 \text{ mm}
\]

\[
t = 0.01d + 0.22 \text{ in.}
\]

where

\[
t = \text{thickness of coaming, in mm (in.)}
\]

\[
d = \text{diameter of ventilator, in mm (in.), but not less than 200 mm (7.5 in.)}
\]

The maximum steel coaming plate thickness required is 10 mm (0.40 in.). The coamings are to be effectively secured to the deck. Coamings which are more than 900 mm (35.5 in.) high and which are not supported by adjacent structures are to have additional strength and attachment. Ventilators passing through superstructures other than enclosed superstructures are to have substantially constructed coamings of steel or equivalent material at the freeboard deck. Where a fire damper is located within a ventilation coaming, an inspection port or opening at least 150 mm (6 in.) in diameter is to be provided in the coaming to facilitate survey of the damper without disassembling the coaming or the ventilator. The closure provided for the inspection port or opening is to maintain the watertight integrity of the coaming and, if appropriate, the fire integrity of the coaming.

Coaming plate thickness of material other than steel will be specially considered.

9.3.2 Coaming Height
Ventilators in Position 1 are to have coamings at least 900 mm (35.5 in.) high. Ventilators in Position 2 are to have coamings at least 760 mm (30 in.) high. For definitions of Position 1 and Position 2, see 3-2-9/3.

9.3.3 Means for Closing Ventilators
Except as provided below, ventilator openings are to be provided with efficient, permanently attached closing appliances. In craft measuring 24 m (79 ft) or more in length (as defined in the International Convention on Load Lines, 1966), ventilators in Position 1, the coamings of which extend to more than 4.5 m (14.8 ft) above the deck and in Position 2, the coamings of which extend to more than 2.3 m (7.5 ft) above the deck, need not be fitted with closing arrangements.

These coaming height requirements may be modified in craft measuring less than 24 m (79 ft) in length.
9.5 **Tank Vents and Overflows**
Tank vents and overflows are to be in accordance with the requirements of 4-4-3/9.1 and 4-4-3/11 of these Rules and, where applicable, the requirements given below in 3-2-11/9.7.

9.7 **Ventilators, Tank Vents and Overflows on the Fore Deck**

9.7.1 **Application**
The requirements of this paragraph applies to all ventilators, tank vents and overflows located on the exposed fore deck within the forward 0.25\(L\) on craft with length\( L\) (as defined in 3-1-1/3) not less than 80 meters (263 feet) and where the height of the exposed deck in way of the item is less than 0.1\(L\) or 22 meters (72 ft) above the summer load waterline, whichever is the lesser.

9.7.2 **Applied Loading to the Air Pipes and Ventilators**

9.7.2(a) **Pressure.**
The pressures \(p\), in \(kN/m^2\) (\(tf/m^2\), \(Lt/ft^2\)), acting on air pipes, ventilator pipes and their closing devices, may be calculated from:

\[
p = f \rho V^2 C_d C_s C_p \text{ kN/m}^2 \text{ (tf/m}^2\text{, Lt/ft}^2\text{)}
\]

where:

\[
f = 0.5 \ (0.05, 0.0156)
\]
\[
\rho = \text{density of sea water, } 1.025 \text{ t/m}^3 \ (1.025 \text{ t/m}^3, 0.0286 \text{ Lt/ft}^3)
\]
\[
V = \text{velocity of water over the fore deck, } 13.5 \text{ m/sec (44.3 ft/sec)}
\]
\[
C_d = \text{shape coefficient}
\]
\[
= 0.5 \text{ for pipes}
\]
\[
= 1.3 \text{ for pipes or ventilator heads in general}
\]
\[
= 0.8 \text{ for pipes or ventilator heads of cylindrical form with its axis in the vertical direction}
\]
\[
C_s = \text{slamming coefficient, 3.2}
\]
\[
C_p = \text{protection coefficient:}
\]
\[
= 0.7 \text{ for pipes and ventilator heads located immediately behind a breakwater or forecastle}
\]
\[
= 1.0 \text{ elsewhere including immediately behind a bulwark}
\]

9.7.2(b) **Force.**
Forces acting in the horizontal direction on the pipe and its closing device may be calculated from the above pressure using the largest projected area of each component.

9.7.3 **Strength Requirements for Ventilators, Tank Vents and Overflows and their Closing Devices**

9.7.3(a) **Bending Moment and Stress.**
Bending moments and stresses in air pipes and ventilator pipes are to be calculated at critical positions: at penetration pieces, at weld or flange connections, at toes of supporting brackets. Bending stresses in the net section are not to exceed 0.8\(Y\), where \(Y\) is the specified minimum yield stress or 0.2% proof stress of the steel at room temperature. Irrespective of corrosion protection, a corrosion addition to the net section of 2.0 mm (0.08 in.) is then to be applied.

9.7.3(b) **Tank Vents and Overflows**

\(i)\) For standard tank vents and overflows of 760 mm (30 in.) height closed by heads of not more than the tabulated projected area, pipe thicknesses and bracket heights are specified in 3-2-11/9.7.3(e) TABLE 4. Where brackets are required, three or more radial brackets are to be fitted.
ii) Brackets are to be of gross thickness of 8 mm (0.32 in.) or more, of minimum length of 100 mm (4.0 in.), and height according to 3-2-11/9.7.3(e) TABLE 4, but need not extend over the joint flange for the head. Bracket toes at the deck are to be suitably supported.

iii) For other configurations, loads according to 3-2-11/9.7.2 are to be applied, and means of support determined in order to comply with the requirements above. Brackets, where fitted, are to be of suitable thickness and length according to their height.

iv) Final (gross) pipe thickness for air pipes is not to be taken less than as indicated in 4-4-3/9.3

v) The minimum internal diameter of the air pipe or overflow is not to be less than 38 mm.

9.7.3(c) Ventilators

i) For standard ventilators of 900 mm (35.4 in.) height closed by heads of not more than the tabulated projected area, pipe thicknesses and bracket heights are specified in 3-2-11/9.7.3(e) TABLE 5. Brackets, where required, are to be as specified in 3-2-11/9.7.3(b).ii.

ii) For ventilators of height greater than 900 mm (35.4 in.), brackets or alternative means of support are to be provided. Coaming is not to be taken less than as indicated in 3-2-11/9.3 nor in 3-2-11/9.7.3(e) TABLE 4.

9.7.3(d) Components and Connections.

All component parts and connections of the tank vents and overflows or ventilators are to be capable of withstanding the loads defined in 3-2-11/9.7.2.

9.7.3(e) Rotary Heads.

Rotating type mushroom ventilator heads are not to be used for application in this location.

Notes:

1 Brackets [see 3-2-11/9.7.3(b)] need not extend over the joint flange for the head.
2. Brackets are required where the as fitted (gross) thickness is less than 10.5 mm (0.41 in.), or where the tabulated projected head area is exceeded.

Note: For other air pipe heights, the relevant requirements of 3-2-11/9.7.3 are to be applied.

<td></td>
</tr>
</tbody>
</table>

Note: For other ventilator heights, the relevant requirements of 3-2-11/9.7.3 are to be applied.
**General**

Unless otherwise approved, all steel work is to be suitably coated with paint or equivalent. No final painting or coating is to be performed until all surveys and testing have been completed. All areas not being coated are to be protected during painting, and upon completion of the work any paint accidentally applied to the areas are to be removed.

**Preparation**

Surfaces that are to be painted are to be completely free of rust, loose paint, dirt, scale, oil, grease, salt deposits, and moisture. Protective coatings are to be applied as soon as practical after cleaning before corrosion or soil forms on the cleaned surface.

If more than seven days elapse between epoxy coats, the surface should be cleaned prior to an application of a tack coat (1-2 wet mils) before the application of the next full coat.

**Protection of Steel**

5.1 **Preparation**

All steel surfaces that will be coated are to be abrasive blast cleaned. Prior to abrasive blast cleaning, surfaces contaminated with oil or grease are to be cleaned and weld splatters, slag, and flux compounds are to be removed by grinding, sanding, or chipping. In areas where abrasive blasting is not feasible, the surfaces are to be cleaned by mechanical means to remove foreign matter.

Galvanized steels shall be roughened with a light abrasive blast or by mechanical means prior to painting.

5.3 **All Spaces (1 July 2018)**

Unless otherwise approved, all steel surfaces are to be suitably coated with paint and/or cathodic protection, as applicable. For more details, refer to the ABS Guidance Notes on Cathodic Protection of Ships and the ABS Guidance Notes on the Application and Inspection of Marine Coating Systems.

5.5 **Salt Water Ballast Space**

 Tanks or holds for salt water ballast are to have a corrosion-resistant hard type coating such as epoxy or zinc on all structural surfaces. Where a long retention of salt water is expected due to the type of craft or unit, special consideration for the use of inhibitors or sacrificial anodes may be given.

5.7 **Oil Spaces**

Tanks intended for oil need not be coated.
7 Protection of Aluminum

7.1 General
Aluminum alloys intended for hull construction are to be used generally only under conditions that will not induce excessive corrosion. Where exposure to environment that would induce excessive corrosion is expected, suitable coatings, tapes, sacrificial anodes, impressed-current systems or other corrosion prevention measures are to be used. When tapes are used for corrosion protection, they are to be non-wicking and non-water absorbing. Grease containing graphite is not to be used with aluminum, instead, zinc or other suitable base grease is to be used.

7.3 Preparation
All aluminum surfaces that will be coated are to be thoroughly cleaned to bare metal, free of corrosion products, dirt, and other contaminants, by light abrasive blasting. Spot cleaning after blasting can be done by power brushing or orbital sanding.

7.5 Coatings
Coatings are to be applied in accordance with the manufacturer’s instructions, and are to be preceded by appropriate cleaning and possibly chemical conversion of surfaces as may be required in accordance with the manufacturer’s recommendations. Coatings are to be free from voids, scratches or other imperfections that are potential sites for localized corrosion.

The composition of coatings is to be compatible with aluminum. Coatings containing copper, lead, mercury or other metals that can induce galvanic or other forms of corrosion are not to be used. Zinc chromate coatings may be used. Insulating coatings intended to prevent galvanic corrosion are not to contain graphite or other conducting materials.

7.7 Faying Surfaces – Aluminum to Aluminum
Aluminum faying surfaces that will be exposed to weather, seawater, or other corrosive environment are to be suitable coated to minimize crevice corrosion in way of the faying surfaces.

7.9 Faying Surface between Aluminum and Other Metals
7.9.1 Hull
Suitable means are to be taken to avoid direct contact of faying surfaces of aluminum to other metals. When such faying surfaces occur in hull construction, suitable non-wicking and non-water absorbing insulation tapes or coatings are to be used. Faying surfaces between mechanically fastened metal components, except machinery foundations, are to be protected by the use of bedding compounds or adhesives. Other types of joints between aluminum and other metals may be approved in certain applications.

7.9.2 Piping
Suitable means, such as special pipe hangers, are to be used to avoid conductive connections between aluminum hulls and non-aluminum metal piping systems. Where watertightness is required, such as when piping passes through bulkheads, decks, tanktops, and shell, special fittings will be required to maintain isolation between dissimilar metals.

7.9.3 Bearing Areas
Bearing areas such as engine beds, pump foundations, propeller shafts, rudder and other appendages of metals other than aluminum are to be suitably isolated by such means as non-metallic bearing casing, non-conductive packing (not containing graphite or other conductors) or suitable tapes and coatings. Alternative methods for minimizing corrosion at these locations will be specially considered. Wicking-type tapes or water-absorbing packing materials such as canvas should not be used. The metals used for such applications are to be selected to minimize galvanic effects; stainless steels are to be considered. The use of copper-base alloys such as brass or bronze
is generally not recommended where galvanic corrosion is of concern, and these materials may only be used when specially approved. In those cases where the use of dissimilar metals cannot be avoided, or where galvanic corrosion is of concern, such as in wet tanks, a suitable sacrificial anode or impressed current system should be installed.

7.11  **Faying Surface between Aluminum and Non-metals**

Aluminum in contact with wood or insulating-type material is to be protected from the corrosive effects of the impurities in these materials by a suitable coating or covering. Concrete used with aluminum is to be free of additives for cold weather pouring. Preformed glass insulation is recommended for piping insulation. Any adhesives which may be used to connect insulation to aluminum are to be free of agents that would be corrosive to aluminum. Foaming agents harmful to aluminum, such as Freon, are not to be used for insulating foams. Areas where dirt or soot is likely to collect and remain for prolonged periods are to be protected from pitting corrosion by the use of coatings or other suitable means.

7.13  **Corrosion of Wet Spaces**

Suitable means are to be used to avoid arrangements that could induce crevice corrosion in wet spaces. In bilge spaces, chain lockers, and similar locations where exfoliation corrosion may be of concern, appropriate materials suitably heat treated for resistance to this form of corrosion are to be employed.

7.15  **Service at Elevated Temperatures**

For service temperatures of 66°C (150°F) or above, only aluminum alloys and filler metals specially designated for service at these temperatures are to be used.

7.17  **Cathodic Protection for Corrosion Prevention**

For application where corrosion is of concern, consideration is to be given to the use of sacrificial anode or impressed current systems of corrosion control. Details of sacrificial anodes and arrangements are to be submitted for review. Anodes are to be in accordance with ASTM or other recognized standard. When impressed current systems are used, adequate precautions are to be taken that the negative voltage is not excessive.

7.19  **Stray Current Protection**

Precautions are to be taken when in dock to prevent stray currents from welding power or other sources from adversely affecting the aluminum. Whenever possible, the cathodic protection system of the craft should be in place and operating when the craft is in the water. AC power sources are to be insulated from the hull. For battery and other DC power sources, grounding is to be avoided if possible. Where safety considerations require grounding to the hull, the negative pole is to be connected to the hull.

7.21  **Bi-material Joints**

Such joints, when used, may be required to be appropriately painted, coated, wrapped or protected by other methods to prevent galvanic corrosion. Where aluminum is to be joined to other materials, each faying surface is to be suitably coated to minimize corrosion. In addition, when one or both sides of an aluminum or steel connection to dissimilar metal joints are exposed to weather, sea water, or wet spaces, a minimum of 0.5 mm (0.02 in.) of suitable insulation is to be installed between faying surfaces and extended beyond the edge of the joint. Non-welded oil or water stops are to be of plastic insulation tape or equivalent which would provide a suitably corrosion resistant system. Insulating materials are to be non-porous and have mechanical properties suitable for the application.

9  **Protection of Fiber Reinforced Plastic**

9.1  **General**

Cured gel-coat resins and lay-up resin are to be highly resistant to water and other liquid absorption; appropriate materials, lay-up, and lay-up procedures are to be used and manufacturer’s recommendations
followed to attain this. Care is to be taken in the use of laminates containing carbon fibers so that they are not close to or do not induce galvanic corrosion with metal fittings.

9.3 Preparation

Composite surfaces that are not coated in the mold are to be sanded lightly to remove any foreign matter. Care is to be taken not to expose any of the structural glass. Surfaces are to be cleaned with water and solvent to ensure the removal of residual mold release compound, oil, or grease.

9.5 Tanks

In water, fuel oil, or other approved tanks, the resins used are to be compatible with the contents of the tanks; the contents of the tanks are not to affect the cured properties of the tank laminate. The cured laminate is to be highly resistant to absorption of the liquid, and is not to have harmful, deleterious, or undesirable effects on the contents of the tank. The tank is generally to be gel-coated on the inside. See also 3-2-5/5.1.

9.7 Cathodic Protection

Cathodic protection is to be provided where shaft struts, propeller shafts, propellers, rudders, fittings, etc. are constructed of manganese bronze, brass, stainless steel or mild steel. Details of the sacrificial anodes and arrangements are to be submitted for review. Anodes are to be in accordance with ASTM or other recognized standard.
1.1 General

1.1.1 Plans and Specifications
The actual sizes of fillet welds are to be indicated on detail drawings or on a separate welding schedule and submitted for approval in each individual case.

1.1.2 Workmanship
Fillet welds may be made by an approved manual, semi-automatic or automatic process. Completed welds are to be to the satisfaction of the attending Surveyor. The gaps between the faying surfaces of members being joined should be kept to a minimum. Where the opening between members being joined exceeds 1.0 mm (0.04 in.) and is not greater than 5 mm (\(\frac{5}{16}\) in.), the weld leg size is to be increased by the amount of the opening in excess of 2.0 mm (\(\frac{1}{16}\) in.). Spacing between plates forming tee joints is not to exceed 5 mm (0.1875 in.). Where the opening between members is greater than 5 mm (\(\frac{3}{16}\) in.), corrective procedures are to be specially approved by the Surveyor.

1.1.3 Special Precautions
Special precaution such as the use of preheat or low-hydrogen electrodes or low-hydrogen welding processes may be required where small fillets are used to attach heavy plates or sections. When heavy sections are attached to relatively light plating, the weld size may be required to be modified. When terminating an aluminum weld, either continuous or intermittent, crater filling by back stepping is recommended to provide a sound ending for each fillet.

1.1.4 (1 July 2015)
For all welds in ballast tanks required to be in compliance with the IMO PSPC and/or IMO PSPC-COT Regulations, continuous welding is to be adopted.

1.3 Tee Connections
In general, the required size and spacing of the fillets is to be as given in 3-2-13/1.5.

1.3.1 Size of Fillet Welds
Frames, beams, bulkheads stiffeners, floors and intercostals, etc. are to have at least the disposition and sizes of intermittent or continuous fillet welds, as required by 3-2-13/5 TABLE 1. Where it is desirable to substitute continuous welding for intermittent welding, as given in 3-2-13/5 TABLE 1, a reduction from the required size of fillet may be allowed if equivalent strength is provided.

1.3.2 Intermittent Welding at Intersection
Where beams, stiffeners, frames, etc., are intermittently welded and pass through slotted girders, shelves or stringers, there is to be a pair of matched intermittent welds on each side of each such intersection and the beams, stiffeners and frames are to be efficiently attached to the girders, shelves and stringers.
1.3.3 Welding of Longitudinal to Plating
Welding of longitudinals to plating is to have double continuous welds at the ends and in way of transverses equal in length to the depth of the longitudinal. For deck longitudinals only, a matched pair of welds is required at the transverses.

1.3.4 Stiffeners and Webs to Hatch Covers
Unbracketed stiffeners and webs of hatch covers are to be welded continuously to the plating and to the face plate for a length at ends equal to the end depth of the member.

1.5 Fillet Sizes and Spacing
Tee connections are to be formed by continuous or intermittent fillet welds on each side, the leg size, \( w \), of the fillet welds is to be obtained from the following equations:

\[
\begin{align*}
    w &= t_p \times C \times \frac{s}{\ell} + 1.5 \text{ mm} \\
    w &= t_p \times C \times \frac{s}{\ell} + 0.06 \text{ in.}
\end{align*}
\]

where

- \( w \) = size of the weld leg, in mm (in.)
- \( \ell \) = actual length of the weld fillet, clear of crater, in mm (in.). See 3-2-13/5 FIGURE 1
- \( s \) = distance between centers of weld fillets, in mm (in.). See 3-2-13/5 FIGURE 1
- \( t_p \) = thickness of the thinner of the two members being joined, in mm (in.)
- \( C \) = weld factor given in 3-2-13/5 TABLE 1

\( w \) is not to be taken less than \( 0.3t_p \) or 3.5 mm (0.14 in.), whichever is greater.

The throat thickness of the fillet is to be not less than \( 0.7w \).

In calculating weld factors, the leg length of matched fillet weld is to be taken as the designated leg length or \( 0.7t_p + 2.0 \text{ mm (0.7}t_p + 0.08 \text{ in.), whichever is less.} \)

Where it is intended to use continuous fillet welding, the leg size of fillet welds is to be obtained from the above equations taking \( s/\ell \) equal to 1.

For intermittent welding with plate thickness less than 7 mm (0.28 in.) welds are to be staggered.

1.7 Thin Plating
For plating of 6.5 mm (0.25 in.) or less, the requirements of 3-2-13/1.5 may be modified as follows:

\[
\begin{align*}
    W &= t_{p/\ell} \times C \times \frac{s}{\ell} + 2.0[1.25 - (\ell/s)] \text{ mm} \\
    W &= t_{p/\ell} \times C \times \frac{s}{\ell} + 0.08[1.25 - (\ell/s)] \text{ in.} \\
    W_{\text{min}} &= 3.5 \text{ mm (0.14 in.)}
\end{align*}
\]

For plates less than 4.5 mm (0.1875 in.), welds less than required above will be specially considered.

1.9 Length and Arrangement of Fillet
Where an intermittent weld is permitted by 3-2-13/5 TABLE 1, the length of each fillet weld is to be not less than 75 mm (3 in.) for \( t_{p/\ell} \) of 7 mm (0.28 in.) or more, nor less than 65 mm (2.5 in.) for lesser \( t_{p/\ell} \).
The unwelded length is to be not more than $32t_{pe}$.

1.11 Fillet Weld Arrangements

1.11.1 Intersections
Where beams, stiffeners, frames, etc., are intermittently welded and pass through slotted girders, shelves or stringers, there is to be a pair of matched intermittent welds on each side of each such intersection and the beams, stiffeners and frames are to be efficiently attached to the girders, shelves and stringers. The length of the matched intermittent fillet welds is to be $0.125$ times the span or $100$ mm (4 in.), whichever is greater.

1.11.2 Unbracketed End Attachments
Unbracketed beams, frames, etc., and stiffeners of watertight and tank bulkheads and superstructure and house fronts are to have double continuous welds for length at each end equal to the depth of the member but not less than $0.125$ times the span or $100$ mm (4 in.), whichever is greater.

1.11.3 Bracketed End Attachments
Frames, beams, stiffeners etc., are to be lapped onto the bracket a length not less than $1.5$ times the depth of the member, and are to have continuous fillet welds all around. Lapped end connections of longitudinal strength members are also to have a throat size, $t$, such that the total effective area of the lap welding is not less than the area of the member being attached.

1.11.4 Lapped Joints
Lapped joints are typically not to be used in structural applications or on plates greater than $6$ mm (0.25 in.) thick, unless specially approved.

Lapped joints are generally to have a width of overlap not less than twice the thickness of thinner plate plus $25$ mm (1 in.) with welds on both edges of the sizes required by 3-2-13/1.5.

1.11.5 Plug Welds or Slot Welds
Plug welds or slot welds are to be specially approved for particular applications. When approved, an appropriate demonstration that adequate weld penetration and soundness is achieved is to be made to the Surveyor’s satisfaction. When used in the attachment of doublers and similar applications, plug or slot welds may be spaced at 16 times the doubler thickness, but not more than $300$ mm (12 in.) between centers in both directions. In general, elongated slot welds are recommended. For closing plates on rudders, slots are to be $75$ mm (3 in.) in length spaced at $150$ mm (6 in.) between centers. The periphery of the plugs or slots are to be fillet welded, of fillet size, $w$, generally not less than $0.70$ times the plate thickness. Plugs and slots are not to be filled with welded deposit.

3 Bi-material Joints (2015)

Techniques required for joining two different materials are subject to special consideration. The use of explosion bonding may be considered depending on the application and the mechanical and corrosive properties of the joint. The material is to meet the requirements as outlined in Appendix 2-5-A4.

The following drawings/information are to be submitted to the Engineering office that carries out the plan review:

i) Drawing indicating the location on the vessel/craft of the bi-material joint

ii) Appropriate plate thickness and material specification

iii) Butt/fillet welding procedure

iv) Manufacturing procedure and control manual for bi-material joints.
v) Material certificate and test results of the bi-material joints
vi) Calculation of maximum tensile and shear stress for the joints when installed at position

In addition to complying with the above mentioned requirements, the following points are to be considered:

i) Tensile and shear strength of the structural arrangement is to comply with the requirements as mentioned in Appendix 2-5-A4.

ii) Suitable insulation is to be provided for the joints.

iii) Such joints are required to be appropriately painted, coated, wrapped or protected by other methods to prevent the galvanic corrosion (3-2-12/7.21).

5 Alternatives

The foregoing are considered minimum requirements for welding in hull construction, but alternative methods, arrangements and details will be considered for approval. Fillet weld sizes may be determined from structural analyses based on sound engineering principles, provided they meet the overall strength standards of the Rules.

1 Application

Bending moments, shear forces and reaction forces of rudders, stocks and bearings may be calculated according to this Appendix for the types of rudders indicated. Moments and forces on rudders of different types or shapes than those shown are to be calculated using alternative methods and will be specially considered.

3 Spade Rudders (2014)

3.1 Rudder

3.1.1 Shear Force

For regular spade rudders as shown in 3-2-A1/3.7 FIGURE 1(a), the shear force, \( V(z) \), at a horizontal section of the rudder above baseline is given by the following equation:

\[
V(z) = \frac{z c_R}{A} \left[ c_\ell + \frac{z}{2 c_R} (c_u - c_\ell) \right] \text{kN (tf, Ltf)}
\]

where

\[
\begin{align*}
  z & = \text{distance from the rudder baseline to the horizontal section under consideration, in m (ft)} \\
  c_R & = \text{rudder force, as defined in 3-2-8/3, in kN (tf, Ltf)} \\
  A & = \text{total projected area of rudder blade in m}^2 (\text{ft}^2), \text{as defined in 3-2-8/3}
\end{align*}
\]

\( c_\ell, c_u \) and \( \ell_R \) are dimensions as indicated in 3-2-A1/3.7 FIGURE 1(a), in m (ft).

For spade rudders with embedded rudder trunks let deep in the rudder blade, as shown in 3-2-A1/3.7 FIGURE 1(b), the shear forces at rudder horizontal sections above rudder baseline in areas \( A_1 \), and \( A_2 \), are given by the following equations:

\[
\begin{align*}
  V(z')_1 &= \frac{z' c_{R1}}{A_1} \left[ c_u - \frac{z'}{2 c_{R1}} (c_u - c_b) \right] \text{kN (tf, Ltf), over area } A_1 \\
  V(z)_2 &= \frac{z c_{R2}}{A_2} \left[ c_b - \frac{z}{2 c_{R2}} (c_b - c_l) \right] \text{kN (tf, Ltf , over area } A_2
\end{align*}
\]

where

\[
\begin{align*}
  z' &= \ell_R - z \\
  c_{R1} &= \text{rudder force over rudder area } A_1, \text{in kN (tf, Ltf)} \\
  &= \frac{A_1}{A} c_R
\end{align*}
\]
\[ C_{R2} = \text{rudder force over rudder area } A_2, \text{ in kN (tf, Ltf)} \]

\[ = \frac{A_2}{A} C_R \]

\[ A_1 = \text{partial rudder blade area above neck bearing and below rudder top, in } \text{mm}^2 (\text{ft}^2) \]

\[ A_2 = \text{partial rudder blade area above rudder baseline and below neck bearing, in } \text{mm}^2 (\text{ft}^2) \]

\[ z, A, \text{ and } C_R \text{ are as indicated in 3-2-A1/3.1.1.} \]

\[ c_\ell, c_b, c_u, \ell_u, \text{ and } \ell_b \text{ are dimensions as illustrated in 3-2-A1/3.7 FIGURE 1(b).} \]

### 3.1.2 Bending Moment

For regular spade rudders, bending moment, \( M(z) \), at a horizontal section \( z \) meters (feet) above the baseline of the rudder is given by the following equations:

\[ M(z) = \frac{z^2 C_R}{2A} \left[ c_\ell + \frac{z}{3C_R}(c_u - c_\ell) \right] \text{ kN - m, (tf - m, Ltf - ft)} \]

For spade rudders with embedded rudder trunk, the bending moment at a horizontal section within area \( A_1 \) is obtained from the following:

\[ M(z')_1 = \frac{(z')^2 C_{R1}}{2A_1} \left[ c_u - \frac{z'}{3C_{R1}}(c_u - c_b) \right] \text{ kN - m, (tf - m, Ltf - ft)} \]

With the maximum bending moment \( M_1 \) over area \( A_1 \) equals to:

\[ M_1 = C_{R1} \ell_\ell \left[ 1 - \frac{2c_b + c_u}{3(c_b + c_u)} \right] \text{ kN - m, (tf - m, Ltf - ft)} \]

For spade rudders with embedded rudder trunk, the bending moment at a horizontal section within area \( A_2 \) is obtained from the following:

\[ M(z)_2 = \frac{z^2 C_{R2}}{2A_2} \left[ c_\ell + \frac{z}{3C_{R2}}(c_u - c_\ell) \right] \text{ kN - m, (tf - m, Ltf - ft)} \]

With the maximum bending moment \( M_2 \) over area \( A_2 \) equals to:

\[ M_2 = C_{R2} \ell_b \frac{2c_\ell + c_b}{3(c_\ell + c_b)} \text{ kN - m, (tf - m, Ltf - ft)} \]

where \( z, z', C_{R1}, C_{R2}, A_1, A_2, c_\ell, c_u \) and \( \ell_R \) are as defined in 3-2-A1/3.1.1.

### 3.3 Lower Stock

#### 3.3.1 Shear Force

For regular spade rudder, the shear force, \( V_\ell \), at any section of the lower stock between the top of the rudder and the neck bearing is given by the following equation:

\[ V_\ell = C_R \text{ kN (tf, Ltf)} \]

For spade rudder with embedded rudder trunk, the shear force at any section of the stock between the top of the rudder and the neck bearing is given by the following equation:

\[ V_\ell = \frac{M_2 - M_1}{\ell_u + \ell_\ell} \text{ kN (tf, Ltf)} \]
where $C_R$, $\ell_\ell$, and $\ell_u$ are as defined in 3-2-A1/3.1.1.

### 3.3.2 Bending Moment at Neck Bearing (2017)

For regular spade rudder, the bending moment in the rudder stock at the neck bearing, $M_n$, is given by the following equation:

$$M_n = C_R \left[ \ell_\ell + \frac{\ell_R (2\ell_\ell + c_u)}{3(\ell_\ell + c_u)} \right] \text{ kN} \cdot \text{m} (\text{tf} \cdot \text{m}, \text{Ltf} \cdot \text{ft})$$

where

- $C_R = \text{rudder force as defined in 3-2-8/3}$
- $c_\ell, c_u, \ell_\ell$ and $\ell_R$ are dimensions as indicated in 3-2-A1/3.7 FIGURE 1, in m (ft).

For spade rudder with embedded rudder trunk, the bending moment in the rudder stock at the neck bearing is given by the following equation:

$$M_n = M_2 - M_1 \text{ kN} \cdot \text{m} (\text{tf} \cdot \text{m}, \text{Ltf} \cdot \text{ft})$$

where $M_1$ and $M_2$ are as defined in 3-2-A1/3.1.2.

Where partial submergence of the rudder leads to a higher bending moment in the rudder stock at the neck bearing (compared with the fully submerged condition), $M_n$ is to be calculated based on the most severe partially submerged condition.

### 3.5 Moment at Top of Upper Stock Taper

For regular spade rudder, the bending moment in the upper rudder stock at the top of the taper, $M_t$, is given by the following equation:

$$M_t = C_R \left[ \ell_\ell + \frac{\ell_R (2\ell_\ell + c_u)}{3(\ell_\ell + c_u)} \right] \times \left[ \frac{(\ell_u + \ell_R + \ell_\ell - z_t)}{\ell_u} \right] \text{ kN} \cdot \text{m} (\text{tf} \cdot \text{m}, \text{Ltf} \cdot \text{ft})$$

For spade rudder with embedded rudder trunk, the bending moment in the upper rudder stock at the top of the taper is given by the following equation:

$$M_t = M_R \left[ \frac{(\ell_u + \ell_R - z_t)}{\ell_u} \right] \text{ kN} \cdot \text{m} (\text{tf} \cdot \text{m}, \text{Ltf} \cdot \text{ft})$$

where

- $z_t = \text{distance from the rudder baseline to the top of the upper rudder stock taper in m (ft)}$
- $C_R = \text{rudder force, as defined in 3-2-A1/3.1.1}$
- $M_R = \text{is the greater of } M_1 \text{ and } M_2, \text{ as defined in 3-2-A1/3.1.2}$
- $c_\ell, c_u, \ell_\ell, \ell_u$ and $\ell_R$ are dimensions as indicated in 3-2-A1/3.7 FIGURE 1, in m (ft).

### 3.7 Bearing Reaction Forces

For regular spade rudder, the reaction forces at the bearings are given by the following equations:
\[ P_u = \text{reaction force at the upper bearing} \]
\[ = -\frac{M_n}{\ell_u} \text{kN (tf, Ltf)} \]
\[ P_n = \text{reaction force at the neck bearing} \]
\[ = C_R + \frac{M_n}{\ell_u} \text{kN (tf, Ltf)} \]

For spade rudder with embedded rudder trunk, the reaction forces at the bearings are given by the following equations:

\[ P_u = -\frac{M_n}{\ell_u + \ell_l} \text{kN (tf, Ltf)} \]
\[ P_n = C_R + P_u \text{kN (tf, Ltf)} \]

where

\[ M_n = \text{bending moment at the neck bearing, as defined in 3-2-A1/3.3.2} \]
\[ C_R = \text{rudder force, as defined in 3-2-8/3} \]

\[ \ell_u \] is as indicated in 3-2-A1/3.7 FIGURE 1, in m (ft).
5 **Rudders Supported by Shoepiece**

5.1 **Shear Force, Bending Moment and Reaction Forces**

Shear force, bending moment and reaction forces may be calculated according to the model given in 3-2-A1/5.1 FIGURE 2.

---

**FIGURE 1**

*Spade Rudder (2014)*

7  Rudders Supported by a Horn with One Pintle

7.1  Shear Force, Bending Moment and Reaction Forces

Shear force, bending moment and reaction forces are to be assessed by the simplified beam model shown in 3-2-A1/7.1 FIGURE 3.

\[ w_{R1} = \text{rudder load per unit length above pintle} \]
\[ = \frac{C_{R1}}{\ell_{R1}} \text{ kN/m (tf/m, Ltf/ft)} \]
\[ w_{R2} = \text{rudder load per unit length below pintle} \]
\[ = \frac{C_{R2}}{\ell_{R2}} \text{ kN/m (tf/m, Ltf/ft)} \]

where

\[ C_{R1} = \text{rudder force, as defined in 3-2-8/3.3} \]
\[ C_{R2} = \text{rudder force, as defined in 3-2-8/3.3} \]
\[ k_h = \text{spring constant reflecting support of the horn} \]
\[ = \frac{1}{\ell_h^3} \frac{\sum (s_i^4)/4}{n_b d^2} \text{ kN/m (tf/m, Ltf/ft)} \]
\[ n_b = 4.75 (0.485, 215) \]
\[ n_t = 3.17 (0.323, 143) \]
\[ a = \text{mean area enclosed by the outside lines of the rudder horn, in cm}^2 (\text{in}^2) \]
\[ s_i = \text{the girth length of each segment of the horn of thickness } t_i, \text{ in cm (in.)} \]
\[ t_i = \text{the thickness of each segment of horn outer shell of length } s_i, \text{ in cm (in.)} \]
\[ I_h = \text{moment of inertia of horn section at } \ell_h \text{ about the longitudinal axis, in cm}^4 (\text{in}^4) \]
\[ e, \ell_h, \ell_{R1} \text{ and } \ell_{R2} \text{ are dimensions as indicated in 3-2-A1/7.1 FIGURE 3, in m (ft).} \]
9. **Rudders Supported by a Horn Arranged with Two Pintles (Supports) (1 July 2016)**

9.1 **Shear Force, Bending Moment and Reaction Forces**

Shear force, bending moment and reaction forces are to be assessed by the simplified beam model shown in 3-2-A1/9.1 FIGURE 4.

\[
\begin{align*}
  w_{R1} &= \text{rudder load per unit length above lower rudder support/pintle} \\
  &= \frac{C_{R1}}{\ell_{R1}} \text{kN/m (tf/m, Ltf/ft)} \\
  w_{R2} &= \text{rudder load per unit length below lower rudder support/pintle} \\
  &= \frac{C_{R2}}{\ell_{R2}} \text{kN/m (tf/m, Ltf/ft)}
\end{align*}
\]

where

\[
\begin{align*}
  C_{R1} &= \text{rudder force, as defined in 3-2-11/3.3} \\
  C_{R2} &= \text{rudder force, as defined in 3-2-11/3.3}
\end{align*}
\]

\(\ell_{R1}\) and \(\ell_{R2}\) are dimensions as indicated in 3-2-A1/9.1 FIGURE 4, in m (ft).
In 3-2-A1/9.1 FIGURE 4 the variables $K_{11}$, $K_{22}$, $K_{12}$ are rudder horn compliance constants calculated for rudder horn with 2-conjugate elastic supports. The 2-conjugate elastic supports are defined in terms of horizontal displacements, $y_i$, by the following equations:

- At the lower rudder horn bearing:
  \[ y_1 = -K_{12}B_2 - K_{22}B_1 \quad \text{m(ft)} \]
- At the upper rudder horn bearing:
  \[ y_2 = -K_{11}B_2 - K_{12}B_1 \quad \text{m(ft)} \]

where

- $y_1, y_2$ = horizontal displacement at lower and upper rudder horn bearings, respectively
- $B_1, B_2$ = horizontal support force, in kN (tf, Ltf), at lower and upper rudder horn bearings, respectively
- $K_{11}, K_{22}, K_{12}$ = spring constant of the rudder support obtained from the following:
  \[ K_{11} = m \left[ 3 \lambda 3 \\frac{3EJ_{1h}}{2EI_{1h}} + \frac{e^2}{GJ_{th}} \right] \quad \text{m/kN(m/ft, ft/Ltf)} \]
  \[ K_{22} = m \left[ 3 \lambda 3 \\frac{3EJ_{1h}}{2EI_{1h}} + \frac{e^2}{GJ_{th}} \right] \quad \text{m/kN(m/ft, ft/Ltf)} \]
  \[ K_{12} = m \left[ 3 \lambda 3 \\frac{3EJ_{1h}}{2EI_{1h}} + \frac{e^2}{GJ_{th}} \right] + \frac{4(d - \lambda)^2}{EI_{1h}} + \frac{(d - \lambda)^3}{3EI_{2h}} \quad \text{m/kN(m/ft, ft/Ltf)} \]
- $m = 1.00 \ (9.8067, 32.691)$
- $d$ = height of the rudder horn, in m (ft), defined in 3-2-A1/9.1 FIGURE 4. This value is measured downwards from the upper rudder horn end, at the point of curvature transition, to the mid-line of the lower rudder horn pintle.
- $\lambda$ = length, in m (ft), as defined in 3-2-A1/9.1 FIGURE 4. This length is measured downwards from the upper rudder horn end, at the point of curvature transition, to the mid-line of the upper rudder horn bearing. For $\lambda = 0$, the above formulae converge to those of spring constant $k_h$ for a rudder horn with 1-pintle (elastic support), and assuming a hollow cross section for this part.
- $e$ = rudder-horn torsion lever, in m (ft), as defined in 3-2-A1/9.1 FIGURE 4 (value taken at vertical location $\ell_{th}/2$).
- $E$ = Young’s modulus of the material of the rudder horn in kN/m$^2$ (tf/m$^2$, Ltf/in$^2$)
- $G$ = modulus of rigidity of the material of the rudder horn in kN/m$^2$ (tf/m$^2$, Ltf/in$^2$)
- $J_{1h}$ = moment of inertia of rudder horn about the x axis, in m$^4$ (ft$^4$), for the region above the upper rudder horn bearing. Note that $J_{1h}$ is an average value over the length $\lambda$ (see 3-2-A1/9.1 FIGURE 4).
- $J_{2h}$ = moment of inertia of rudder horn about the x axis, in m$^4$ (ft$^4$), for the region between the upper and lower rudder horn bearings. Note that $J_{2h}$ is an average value over the length $d - \lambda$ (see 3-2-A1/9.1 FIGURE 4).
- $J_{th}$ = torsional stiffness factor of the rudder horn, in m$^4$ (ft$^4$)
  \[ J_{th} = \sum_{i=1}^{n} \frac{w_i}{t_i} \quad \text{for any thin wall closed section, in m}^4 (\text{ft}^4) \]
Note that the $J_{th}$ value is taken as an average value, valid over the rudder horn height.

$F_T = \text{mean of areas enclosed by outer and inner boundaries of the thin walled section of rudder horn, in m}^2$ (ft$^2$)

$u_i = \text{length, in mm (in.), of the individual plates forming the mean horn sectional area}$

$t_i = \text{thickness, in mm (in.), of the individual plates mentioned above}$

PART 3

CHAPTER 2 Hull Structures and Arrangements

APPENDIX 2 Guidance on Analysis of the Cross Deck Structure of a Multi-Hull Craft

Note: This Appendix gives guidance on the analysis of a standard cross deck structure (similar to 3-2-A2/FIGURE 1) of a multi-hulled craft. The analysis includes the determination of the craft’s transverse bending stress, transverse shear stress, and the torsional stress acting on each element. The analysis of cross decks that are of advanced design or material will be specially considered.

FIGURE 1
Typical Geometry of Centerline Section of Cross Deck

1 Transverse Bending and Shear Stress

The transverse bending and shear stress of the cross structure are obtained by the following equations and are less than the allowable stresses defined in 3-2-1/3.5.3:

\[
\sigma_t = \frac{10M_{tb}}{SM_t} \text{ N/mm}^2
\]

\[
\sigma_t = \frac{M_{tb}}{SM_t} \text{ psi}
\]

\[
\tau_a = \frac{10Q_t}{A_t} \text{ N/mm}^2
\]

\[
\tau_a = \frac{Q_t}{A_t} \text{ psi}
\]

where

\(\sigma_t\) = transverse bending stress of the cross deck structure, in N/mm\(^2\) (psi)

\(M_{tb}\) = design transverse bending moment as defined in 3-2-1/3.3, in kN-m (ft-lbs)

\(SM_t\) = offered transverse section modulus of the cross deck, in cm\(^3\)-m (in\(^3\)-ft)

\(\tau_a\) = transverse shear stress of the cross deck structure, in N/mm\(^2\) (psi)

\(Q_t\) = design vertical shear force as defined in 3-2-1/3.3, in kN (lbs)

\(A_t\) = offered shear area of the cross structure, in cm\(^2\) (in\(^2\))
3  Center of Torsional Rotation

The center of torsional rotation of the cross deck structure can be determined by the following formula:

\[ L_c = \frac{\sum_{i=1}^{n} k_i x_i}{\sum_{i=1}^{n} k_i} \text{ cm (in.)} \]

where

- \( k_i \) = element stiffness
- \( x_i \) = longitudinal distance from forward perpendicular, in cm (in.)
- \( n \) = total number of elements in the cross deck structure
- \( E_i \) = modulus of elasticity of the material, for each element, kN/m (psi)
- \( I_i \) = moment of inertia of the element being considered, in m^4 (in^4)
- \( L_i \) = span of cross structure, in m (in.), see 3-2-A2/3 FIGURE 2.

FIGURE 2
Span of Cross Structure

5  Maximum Bending Stress on Each Element

The maximum bending stress on each element is to be less than the allowable torsional stress defined in 3-2-1/3.5.3

5.1  Deflection

The total amount that each element deflects can be determined by the following formula:
\[
\delta_i = \frac{100000M_{tt}x_{ci}}{\sum_{i=1}^{n} x_{ci}^2 K_i} \text{ m}
\]
\[
\delta_i = \frac{12M_{tt}x_{ci}}{\sum_{i=1}^{n} x_{ci}^2 k_i} \text{ in.}
\]

where

\(\delta_i\) = deflection of each member, in m (in.)

\(M_{tt}\) = design torsional moment acting upon the transverse structure connecting the hulls, as determined 3-2-1/3.3, in kN\cdot m (ft-lbs)

\(x_{ci}\) = \(x_i - L_c\), in cm (in.)

\(x_i\), \(L_c\) and \(k_i\) are as defined in 3-2-A2/1.

5.3 Bending Moment

The bending moment that is acting on each element is determined by the following formula:

\[
BM_i = \frac{P_L d_i}{2}
\]

where

\(BM_i\) = bending moment that is acting on the element under consideration, in N\cdot m (in-lbs)

\(P_L\) = \(\delta_i k_i\), force that is acting on the element, in N (lbs)

\(L_i\) = as defined in 3-2-A2/1

\(\delta_i\) = as defined in 3-2-A2/5.1

\(k_i\) = as defined in 3-2-A2/1

5.5 Maximum Stress

The maximum stress that is applied on each element can be determined by the following formula:

\[
\sigma_i = \frac{1000BM_i}{SM_i} \text{ kN/m}^2
\]

\[
\sigma_i = \frac{BM_i}{SM_i} \text{ psi}
\]

where

\(\sigma_i\) = maximum stress that is acting upon the element, in kN/m\(^2\) (psi)

\(BM_i\) = bending moment as defined, in 3-2-A2/5.3

\(SM_i\) = section modulus of the element being considered, in cm\(^3\) (in\(^3\))

5.7 Maximum Shear Stress on Each Element

The maximum shear stress on each element is to be less than the allowable transverse shear stress defined in 3-2-1/3.5.3.
\[ \tau_i = \frac{10P_i}{A_{wi}} \text{ kN/m}^2 \]

\[ \tau_i = \frac{P_i}{A_{wi}} \text{ psi} \]

where

\( \tau_i \) = maximum shear stress that is acting upon the element, in kN/m\(^2\) (psi)

\( P_i \) = force acting upon the element, in N (lbs), as defined in 3-2-A2/5.3

\( A_{wi} \) = area of the web of the element being considered, in cm\(^2\) (in\(^2\))
PART 3

CHAPTER 2 Hull Structures and Arrangements

APPENDIX 3 Alternative Method for the Determination of “V” Shaft Strut Requirements

1 General

The method outlined below may be used as an alternative to the method given in 3-2-7/9. Other alternatives may be considered providing they address loadings from unbalanced centrifugal forces from the propeller, hydrodynamic forces, inertial forces from ship motions, gravity forces from shaft and propeller, and vibrations resulting from all intended conditions.

FIGURE 1 Strut Dimensions

3 Loads and Moments Acting on Strut

The governing loads and moments acting on the shaft strut are as follows:

\[ M_1 = c_1 d_p \left( \frac{W_p}{c_0} \left( \frac{R}{1000} \right)^2 + c_2 \frac{U_p}{V} \right) \text{ kN} - \text{m (tf} - \text{m, lbf} - \text{in)} \]
\[ M_2 = c_3 S M_s \sigma_{ys} \text{ kN-m (tf-m, in-lbf)} \]
\[ F_3 = S M_s \sigma_{ys} / d_s \text{ kN (tf, lbf)} \]

where

- \( c_0 = 1 \) (1, 1000)
- \( c_1 = 0.138 \) (0.138, 3.5)
- \( c_2 = 0.454 \) (0.034, 3.0)
- \( c_3 = 3.0 \times 10^{-4} \) (3.0 \( \times 10^{-4} \), 300)
- \( d_p \) = diameter of the propeller, in m (in.)
- \( W_p \) = weight of the propeller, in kN (tf, lbf)
- \( \ell_p \) = length of the overhang, in m (in.), see 3-2-A3/1 FIGURE 1
- \( R \) = maximum rated RPM of the shaft
- \( H_p \) = power at maximum rated speed, in kW (PS, hp)
- \( V \) = maximum calm water speed of the craft, in knots
- \( S M_s \) = offered section modulus of the shaft, in cm^3 (in^3)
- \( d_s \) = offered diameter of the shaft, in mm (in.)
- \( \sigma_{ys} \) = yield strength of the shaft, in N/cm^2 (kgf/cm^2, psi)

### 5 Required Section Modulus of Strut at the Barrel

\[ S M_{st} = 1000 C_1 [M + F_3 (\ell_p \sin \phi / 1000)] \sigma_y \text{ cm}^3 \]

\[ S M_{st} = C_1 (M + F_3 \ell_p \sin \phi) / \sigma_y \text{ in}^3 \]

\[ C_1 \sqrt{(C_2 / \sin \theta)^2 + (0.5 / \cos \theta)^2} \]

\[ C_2 = \left[ 2 - (\ell_p \ell_s) - (\ell_p \ell_s)^2 \right] / \left[ 4 \left[ 1 + (\ell_p \ell_s) + (\ell_p \ell_s)^2 \right] \right] \]

where

- \( M \) = the greater of \( M_1 \) or \( M_2 \), as defined in 3-2-A3/3, in kN-m (in-lbf)
- \( \ell_p \) = distance from center of strut barrel to the connection of the strut, in mm (in.), see 3-2-A3/1 FIGURE 1
- \( \phi \) = cant angle of strut, in degrees, see 3-2-A3/1 FIGURE 1
- \( \sigma_y \) = yield strength for steel struts or the welded yield strength of aluminum struts, in kN/mm^2 (psi)
- \( \theta \) = vee angle of strut in degrees, see 3-2-A3/1 FIGURE 1
- \( \ell_s \) = distance from center of strut barrel to the hull, in mm (in.), see 3-2-A3/1 FIGURE 1

### 7 Required Section Modulus of Strut at the Hull

\[ S M_{st} = 1000 C_1 [M + F_3 (\ell_s \sin \phi / 1000)] / \sigma_y \text{ cm}^3 \]
\[ S_{M_{st}} = \frac{C_1(M + F_3\ell_s\sin\phi)}{\sigma_y} \text{ in}^1 \]

where \( C_1, M, F_3, \ell_s, \phi \) and \( \sigma_y \) are as defined in 3-2-A3/5.

9 Requirements for Struts Constructed of Aluminum

The required stiffness, \( EI \), for aluminum strut is to be 90% of a strut constructed of ABS grade A steel that meets the requirements in 3-2-A3/5 and 3-2-A3/7.

PART 3

CHAPTER 3 Subdivision and Stability

SECTION 1 General Requirements

1 General
Craft of the following categories are to have subdivision and stability in accordance with the criteria as shown.

3 Criteria

3.1 Intact Stability
All craft which have a length of 24 m (79 ft) or over as defined in the International Convention on Load Lines are to have intact stability guidance as required by Regulation 10 of the International Convention on Load Lines. Following criteria may be used for classification purposes:

3.1.1 For all cargo craft ≥ 500 GT making voyages that are no more than 8 hours at operational speed from a place of refuge and having design speeds greater than 3.7\(\frac{V}{1/6}\) m/sec (7.19\(\frac{V}{1/6}\) knots, 3.97\(\frac{V}{1/6}\) knots) – IMO International Code of Safety for High-Speed Craft – Chapter 2.

3.1.2 For all passenger craft making voyages that are no more than 4 hours at operational speed from a place of refuge and having design speeds greater than 3.7\(\frac{V}{1/6}\) m/sec (7.19\(\frac{V}{1/6}\) knots, 3.97\(\frac{V}{1/6}\) knots) – IMO International Code of Safety for High-Speed Craft – Chapter 2.

3.1.3 Other craft of all sizes – International Code on Intact Stability (2008 IS Code)

where

\[ V = \] volumetric displacement of the vessel in the design condition in \(m^3\) (\(ft^3\))
\[ GT = \] the gross tonnage as defined in 3-1-1/19

In case the above criteria are not applicable to a particular craft, the intact stability will be reviewed by ABS in accordance with other recognized criteria appropriate to the craft's type, size, and intended service.

3.3 Subdivision and Damage Stability
Craft of applicable size, type, and service are to have subdivision and damage stability as required by the International Code of Safety for High-Speed Craft, or the International Convention for the Safety of Life at Sea, 1974, as amended as follows:
3.3.1
Passenger craft making voyages that are no more than 4 hours at operational speed and having design speeds greater than \(3.7 \sqrt[6]{\psi} \text{ m/sec} \) (\(7.19 \sqrt[6]{\psi} \text{ knots} \), \(3.97 \sqrt[6]{\psi} \text{ knots}\)) – IMO International Code of Safety for High-Speed Craft – Chapter 2.

3.3.2
Other passenger craft – SOLAS Regulation II-1/4 through 8

3.3.3
Cargo craft \(\geq 500\) GT making voyages that are no more than 8 hours at operation speed and having design speeds greater than \(3.7 \sqrt[6]{\psi} \text{ m/sec} \) (\(7.19 \sqrt[6]{\psi} \text{ knots} \), \(3.97 \sqrt[6]{\psi} \text{ knots}\)) – IMO International Code of Safety for High-Speed Craft – Chapter 2.

3.3.4
Other cargo craft \(\geq 500\) GT – SOLAS Regulation II-1/5 through 7-3.

5 Review Procedures

5.1 Administration Review
When the craft is issued an International Load Line Certificate, Passenger Ship Safety Certificate, Cargo Ship Safety Construction Certificate, or High-Speed Craft Safety Certificate by the flag Administration or its agent other than ABS, such Certificate will be accepted as evidence that the craft has subdivision and stability in accordance with the above criteria.

Where the Administration undertakes the review of subdivision and stability and ABS is issuing the above Certificate, the acceptance of subdivision and stability by the Administration will be required before the certificate is issued.

5.3 ABS Review
In all other cases the information and calculations for subdivision and stability are to be submitted to ABS for review. Where the intact stability criteria are not applicable to a particular craft, the review will be in accordance with other recognized criteria acceptable to ABS.

7 Onboard Computers for Stability Calculations
The use of onboard computers for stability calculations is not a requirement of class. However, if stability software is installed onboard craft contracted on or after 1 July 2005, it should cover all stability requirements applicable to the craft and is to be approved by ABS for compliance with the requirements of Appendix 3-3-A1, “Onboard Computers for Stability Calculations”.
1 General

1.1 Scope

The scope of stability calculation software is to be in accordance with the stability information as approved by the flag Administration or ABS on behalf of the flag Administration. The software is at least to include all information and perform all calculations or checks as necessary to ensure compliance with the applicable stability requirements.

Approved stability software is not a substitute for the approved stability information, and is used as a supplement to the approved stability information to facilitate stability calculations.

1.3 Design

The input/output information is to be easily comparable with approved stability information so as to avoid confusion and possible misinterpretation by the operator relative to the approved stability information.

An operation manual is to be provided for the onboard computer stability software.

The language in which the stability information is displayed and printed out as well as the operation manual is written is to be the same as used in the craft’s approved stability information. The primary language is to be English.

The onboard computer for stability calculations is to be craft specific equipment and the results of the calculations are to be only applicable to the craft for which it has been approved.

In case of modifications implying changes in the main data or internal arrangement of the craft, the specific approval of any original stability calculation software is no longer valid. The software is to be modified accordingly and reapproved.

3 Calculation Systems

This Appendix covers either system, a passive system that requires manual data entry or an active system, which replaces the manual with the automatic entry with sensors reading and entering the contents of tanks, etc., provided the active system is in the off-line operation mode. However, an integrated system, which controls or initiates actions based on the sensor-supplied inputs is not within the scope of this Appendix.

5 Types of Stability Software (2018)

Four types of calculations performed by stability software are acceptable depending upon a craft’s stability requirements:

- Type 1 Software calculating intact stability only (for vessels not required to meet a damage stability criterion)
● Type 2 Software calculating intact stability and checking damage stability on basis of a limit curve or checking all the stability requirements (intact and damage stability) on the basis of a limit curve.

● Type 3 Software calculating intact stability and damage stability by direct application of preprogrammed damage cases based on the relevant Conventions or Codes for each loading condition

● Type 4 Software calculating damage stability associated with an actual loading condition and actual flooding case, using direct application of user defined damage, for the purpose of providing operational information for safe return to port (SRtP).

Damage stability of both Type 3 and Type 4 stability software is to be based on a hull form model, that is, directly calculated from a full three-dimensional geometric model.

7 Functional Requirements (2018)

7.1 Calculation Program

The calculation program is to present relevant parameters of each loading condition in order to assist the Master in their judgment on whether the craft is loaded within the approval limits. The following parameters are to be presented for a given loading condition:

● Deadweight data
● Lightship data
● Trim
● Draft at the draft marks and perpendiculars
● Summary of loading condition displacement, VCG, LCG and, if applicable, TCG
● Downflooding angle and corresponding downflooding opening (not applicable for Type 2 software which uses limit curve for checking all the stability requirements. However, if intact stability criteria are given in addition to the limit curve, downflooding angle and the corresponding downflooding opening is to be indicated).
● Compliance with stability criteria: Listing of all calculated stability criteria, the limit values, the obtained values and the conclusions (criteria fulfilled or not fulfilled) (not applicable for Type 2 software which uses limit curve for checking all the stability requirements. However, if intact stability criteria are given in addition to the limit curve, the limit values, the obtained values and the conclusion is to be indicated).

7.3 Direct Damage Stability Calculations

If direct damage stability calculations are performed, the relevant damage cases according to the applicable rules are to be pre-defined for automatic check of a given loading condition.

7.5 Warning (2018)

A clear warning is to be given on screen and in hard copy printout if any of the loading limitations are not complied with.

As applicable, loading limitations are to include, but may not be limited to:

● Trim, draft, liquid densities, tank filling levels, initial heel
● Use of limit KG/GM curves in conjunction with above for Type 2
● Restrictions to the stowage height for timber where timber load lines are assigned

7.7 Data Printout

The data are to be presented on screen and in hard copy printout in a clear unambiguous manner.
7.9 Date and Time
The date and time of a saved calculation are to be part of the screen display and hard copy printout.

7.11 Information of Program
Each hard copy printout is to include identification of the calculation program with version number.

7.13 Units
Units of measurement are to be clearly identified and used consistently within a loading calculation.

7.15 Computer Model (2018)
For Type 3 and Type 4 software, the system is to be pre-loaded with a detailed computer model of the complete hull, including appendages, all compartments, tanks and the relevant parts of the superstructure considered in the damage stability calculation, wind profile, down-flooding and up-flooding openings, cross-flooding arrangements, internal compartment connections and escape routes, as applicable and according to the type of stability software.

For Type 1 and Type 2 software, in case a full three dimensional model is used for stability calculations, the requirements of the computer model are to be as per the paragraph above to the extent as applicable and according to the type of stability software.

7.17 Further Requirements for Type 4 Stability Software (2018)
7.17.1 The normal (Type 1, 2 and 3) and SRtP (Type 4) software need not be “totally separated”. Where the normal and SRtP software are not totally separated:

- The function of switching between normal software and Type 4 software is to be provided.
- The actual intact loading condition is to be the same for both functions (normal operation and SRtP); and
- The SRtP module needs only to be activated in case of an incident.

Approval of Type 4 (SRtP) software is for stability only.

7.17.2 In passenger craft which are subject to SRtP and have an onboard stability computer and shore-based support, such software need not be identical.

7.17.3 Each internal space is to be assigned its permeability as shown below, unless a more accurate permeability has been reflected in the approved stability information.

<table>

<tr>
<td>Occupied by machinery</td>
<td></td>
</tr>
</tbody>
</table>
The system is to be capable of accounting for applied moments such as wind, lifeboat launching, cargo shifts and passenger relocation.

The system is to account for the effect of wind by using the method in SOLAS regulation II-1/7-2.4.1.2 as the default, but allow for manual input of the wind speed/pressure if the on-scene pressure is significantly different ($P = 120 \text{ N/m}^2$ equates to Beaufort 6; approximately 13.8 m/s or 27 knots).

The system is to be capable of assessing the impact of open main watertight doors on stability (e.g., for each damage case provided for verification, additional damage stability calculation is to be done and presented, taking into account any watertight door located within the damaged compartment(s)).

The system is to utilize the latest approved lightship weight and center of gravity information.

The output of the software is to be such that it provides the master with sufficient clear unambiguous information to enable quick and accurate assessment of the stability of the craft for any actual damage, the impact of flooding on the means of escape and the controls of devices necessary for managing and/or controlling the stability of the craft.

When the actual loading condition is input in the SRtP software, the following output (intact stability) is to be available:

- Deadweight data
- Lightship data
- Trim
- Heel
- Draft at the draft marks and perpendiculars
- Summary of loading condition displacement, VCG, LCG and, if applicable, TCG
- Downflooding angle and corresponding downflooding opening
- Free surfaces
- GM value
- GZ values relevant to an adequate range of heeling (not less than 60°) available indicatively at the following intervals: 0 5 10 15 20 25 30 40 50 60 deg
- Compliance with relevant intact stability criteria (i.e., 2008 IS Code): listing of all calculated intact stability criteria, the limiting values, the obtained values and the evaluation (criteria fulfilled or not fulfilled)
- GM/KG limiting curve according to SOLAS, Ch II-1, Regulation 5-1

<table>

When the actual loading condition is associated to the actual damage case(s) due to the casualty, the following output (damage stability) is to be available:

- Trim
- Heel
- Draft at the draft marks and perpendiculars
- Progressive flooding angle and corresponding progressive flooding openings
- GM value
- GZ values relevant to an adequate range of heeling (not less than 60°) available indicatively at the following intervals: 0 5 10 15 20 25 30 40 50 60 deg
- Compliance with stability criteria: listing of all calculated stability criteria, the limit values, the obtained values and the conclusions (criteria fulfilled or not fulfilled)
- The survivability criteria for Type 4 software (SRtP) are left to the discretion of the Administration;
- Relevant flooding points (unprotected or weathertight) with the distance from the damage waterline to each point
- List of all flooded compartments with the permeability considered
- Amount of water in each flooded compartment
- Escape route immersion angles
- A profile view, deck views and cross-sections of the craft indicating the flooded water-plane and the damaged compartments

7.17.9

For ro-ro passenger craft, there are to be algorithms in the software for estimating the effect of water accumulation on deck (WOD) (e.g., 1. In addition to the predefined significant wave height, taken from the approved stability document, there is to be possibility for the crew to input manually the significant wave height of the craft navigation area in the system, 2. In addition to the predefined significant wave height, taken from the approved stability document, calculations with two additional significant wave heights are to be submitted for checking the correctness of the algorithms in the software for estimating the effect of WOD). *

* This paragraph applies to Ro-Ro Passenger craft subject to the Stockholm Agreement (IMO Circular Letter No. 1891)

9 Acceptable Tolerances

Depending on the type and scope of programs, the acceptable tolerances are to be determined differently, according to 3-3-A1/9.1 or 3-3-A1/9.3. In general, deviation from these tolerances is not to be accepted unless a satisfactory explanation for the difference is submitted for review and the same is satisfactorily confirmed by ABS that there would be no adverse effect on the safety of the craft.

*Examples of pre-programmed input data include the following:
- Hydrostatic data: Displacement, LCB, LCF, VCB, KMt and MCT vs. draft
- Stability data: KN or MS values at appropriate heel/trim angles vs. displacement, stability limits.
- Compartment data: Volume, LCG, VCG, TCG and FSM vs. level of the compartment’s contents.

*Examples of output data include the following:
- Hydrostatic data: Displacement, LCB, LCF, VCB, KMt and MCT versus draft, as well as actual drafts, trim.
- Stability data: FSC (free surface correction), GZ-values, KG, GM, KG/GM limits, derived stability criteria (e.g., areas under the GZ curve), weather criteria.
- Compartment data: Calculated Volume, LCG, VCG, TCG and FSM vs. level of the compartment’s contents

The computational accuracy of the calculation program results is to be within the acceptable tolerances specified in 3-3-A1/9.1 or 3-3-A1/9.3, of the results using an independent program or the approved stability information with identical input.

9.1 Calculation Program of the Approved Stability Information

Programs which use only pre-programmed data from the approved stability information as the basis for stability calculations are to have zero tolerances for the printouts of input data.

Output data tolerances are to be close to zero. However, small differences associated with calculation rounding or abridged input data are acceptable. Additionally, differences associated with the use of hydrostatic and stability data for trims that differ from those in the approved stability information are acceptable subject to review by ABS.

9.3 Independent Program for Assessment of Stability

Programs which use hull form models as their basis for stability calculations are to have tolerances for the printouts of basic calculated data established against either data from the approved stability information or data obtained using the approval authority’s model. Acceptable tolerances shall be in accordance with 3-3-A1/9.3 TABLE 1.

± 1°

Distance from WL to unprotected and weathertight openings, or other relevant point, if applicable
± 5% or 5 cm, whichever is greater

Areas under righting arm curve
± 5% or 0.0012 mrad

Notes:
1 Deviation in % = [(base value-applicant’s value)/base value] x 100.
where the “base value” may be from the approved stability information or the society’s computer model.

2 When applying a tolerance in 3-3-A1/9.3 TABLE 1 that contains two values, the allowable tolerance is the greater of the two values.

3 Where differences in calculation methodology exist between the programs used in the comparison, this may be a basis for accepting deviations greater than that specified in 3-3-A1/9.3 TABLE 1 provided a software examination is carried out in sufficient detail to clearly document that such differences are technically justifiable.

4 Deviation from these tolerances are not to be accepted unless ABS considers that there is a satisfactory explanation for the difference and that it is clearly evident from ABS’s stability calculations that the deviation does not impact compliance with the required stability criteria for the craft under consideration.

11 Approval Procedure

The onboard software used for stability calculations is subject to approval, which is to include:

- Verification of type approval, if any,
- Verification that the data used is consistent with the current condition of the craft (see 3-3-A1/11.5),
- Verification and approval of the test conditions, and
- Verification that the software is appropriate for the type of craft and stability calculations required.
- Verification that the software is installed so that failure of the primary computer or server does not prevent the stability calculation from being carried out (this is to be demonstrated onboard as noted below)
- Verification of functional requirements under 3-3-A1/7.

The satisfactory operation of the software for stability calculations is to be verified by testing upon installation on the primary computer or server and at least one back-up computer or redundant server onboard (see 3-3-A1/15). A copy of the approved test conditions and the operation manual for the computer/software are to be available onboard.
11.3 General Approval (optional)

Upon receipt of application for general approval of the calculation program, ABS may provide the applicant with test data consisting of two or more design data sets, each of which is to include a craft’s hull form data, compartmentation data, lightship characteristics and deadweight data, in sufficient detail to accurately define the craft and its loading condition.

Acceptable hull form and compartmentation data may be in the form of surface coordinates for modeling the hull form and compartment boundaries (e.g., a table of offsets) or in the form of pre-calculated tabular data (e.g., hydrostatic tables, capacity tables) depending upon the form of data used by the software being submitted for approval. Alternatively, the general approval may be given based on at least two test craft agreed upon between the applicant and ABS.

In general, the software is to be tested for two types of craft for which approval is requested, with at least one design data set for each of the two types. Where approval is requested for only one type of craft, a minimum of two data sets for different hull forms of that type of craft are required to be tested.

For calculation software which is based on the input of hull form data, design data sets are to be provided for three types of craft for which the software is to be approved, or a minimum of three data sets for different hull forms if approval is requested for only one type of craft. Representative craft are those types which, due to their different hull forms, typical arrangements and nature of cargo, require different design data sets.

The test data sets are to be used by the applicant to run the calculation program for the test craft. The results obtained, together with the hydrostatic data and cross-curve data developed by the program, if appropriate are to be submitted to ABS for the assessment of the program’s computational accuracy. ABS is to perform parallel calculations using the same data sets and a comparison of these results will be made against the applicant’s submitted program’s results.

11.5 Specific Approval (2018)

ABS is to verify the accuracy of the computational results and actual craft data used by the calculation program for the particular craft on which the program will be installed.

Upon receipt of application for data verification, ABS and the applicant are to agree on a minimum of four loading conditions, taken from the craft’s approved stability information, which are to be used as the test conditions.

For craft carrying liquids in bulk, at least one of the conditions is to include partially filled tanks. Within the test conditions each compartment is to be loaded at least once. The test conditions normally are to cover the range of load drafts from the deepest envisaged loaded condition to the light ballast condition and are to include at least one departure and one arrival condition.

For Type 4 stability software for SRtP, ABS is to examine at least three damage cases, each of them associated with at least three loading conditions taken from the craft’s approved stability information. Output of the software is to be compared with results of corresponding load/damage case in the approved damage stability booklet or an alternative independent software source.

ABS is to verify that the following data, submitted by the applicant, is consistent with arrangements and most recently approved lightship characteristics of the craft according to current plans and documentation on file with ABS, subject to possible further verification onboard:

- Identification of the calculation program including version number.
- Main dimensions, hydrostatic particulars and, if applicable, the craft profile.
- The position of the forward and after perpendiculars, and if appropriate, the calculation method to derive the forward and after drafts at the actual position of the craft’s draft marks.
Craft lightweight and center of gravity derived from the most recently approved inclining experiment or light weight check.

- Lines plan, offset tables or other suitable presentation of hull form data if necessary for ABS to model the craft.
- Compartment definitions, including frame spacing, and centers of volume, together with capacity tables (sounding/ullage tables), free surface corrections, if appropriate
- Cargo and Consumables distribution for each loading condition.

Verification by ABS does not absolve the applicant and craft owner of responsibility for ensuring that the information programmed into the onboard computer software is consistent with the current condition of the craft.

13 **Operation Manual**

A simple and straightforward operation manual is to be provided, containing descriptions and instructions, as appropriate, for at least the following:

- Installation
- Function keys
- Menu displays
- Input and output data
- Required minimum hardware to operate the software
- Use of the test loading conditions
- Computer-guided dialogue steps
- List of warnings

15 **Installation Testing (2018)**

To ensure correct working of the computer after the final or updated software has been installed, it is the responsibility of the craft’s master to have test calculations carried out according to the following pattern in the presence of the Surveyor:

- From the approved test conditions at least one load case (other than lightship) is to be calculated.

  *Note:*
  
  Actual loading condition results are not suitable for checking the correct working of the computer.

- Normally, the test conditions are permanently stored in the computer.

Steps to be performed:

- Retrieve the test load case and start a calculation run; compare the stability results with those in the documentation.

- Change several items of deadweight (tank weights and the cargo weight) sufficiently to change the draft or displacement by at least 10%. The results are to be reviewed to ensure that they differ in a logical way from those of the approved test condition.

- Revise the above modified load condition to restore the initial test condition and compare the results. Confirm that the relevant input and output data of the approved test condition have been replicated.

- Alternatively, one or more test conditions shall be selected and the test calculation performed by entering all deadweight data for each selected test condition into the program as if it were a proposed
loading. The results shall be verified as identical to the results in the approved copy of the test conditions.

17 **Periodical Testing**

It is the responsibility of the craft’s master to check the accuracy of the onboard computer for stability calculations at each Annual Survey by applying at least one approved test condition.

If the Surveyor is not present for the computer check, a copy of the test condition results obtained by the computer check is to be retained onboard as documentation of satisfactory testing for the Surveyor’s verification.

At each Special Periodical Survey, this checking for all approved test loading conditions is to be done in presence of the surveyor.

The testing procedure is to be carried out in accordance with 3-3-A1/15.

19 **Other Requirements**

The following features are to be provided to the software:

- Protection against unintentional or unauthorized modification of programs and data is to be provided.
- The program is to monitor operations and activate an alarm when the program is incorrectly or abnormally used.
- The program and any data stored in the system are to be protected from corruption by loss of power.
- Error messages with regard to limitations such as filling a compartment beyond capacity, or exceeding the assigned load line, etc. are to be included.

CHAPTER 4 Fire Safety Measures

SECTION 1 Structural Fire Protection

1 General

1.1 SOLAS Application
For classification purposes, the fire and safety measures contained in the International Convention for the Safety of Life at Sea, 1974 (1974 SOLAS), as amended, are applicable to vessels of type, size and service coming under that Convention. This includes the IMO International Code of Safety for High-Speed Craft (HSC Code), incorporated as Chapter X of 1974 SOLAS, as applicable.

This section does not relax the requirements in other sections of the Rules.

Gross tonnage is to be taken as defined in 3-1-1/19.

1.3 Regulation
Regulation means the regulation contained in 1974 SOLAS, as amended. An abbreviated notation is used, e.g., Regulation II-2/5.2 means Regulation 5.2 of Chapter II-2.

1.5 Definitions
See Regulation II-2/3.

1.7 Materials Containing Asbestos
Installation of materials which contain asbestos is prohibited.

3 Passenger Craft
For passenger craft as defined in 1.1 through 1.4 of the HSC Code, the requirements in 7.1 through 7.6 HSC Code are applicable. See also Part 5 Chapter 1.

For all passenger craft subject to 1974 SOLAS as amended, the requirements in Part B, Chapter II-2 are applicable. See also Part 5C, Chapter 7 of the Marine Vessel Rules.

5 Cargo Craft
For cargo craft as defined in 1.1 through 1.4 of the HSC Code, the fire and safety measures contained in Chapter 7 of the IMO International Code of Safety for High-Speed Craft (2000 HSC Code) are applicable.

For all cargo craft subject to 1974 SOLAS as amended, and are defined in Regulation II-2/3.7, the relevant requirements in Part B: Regulation 4, 5, 6; Part C: Regulations 7, 8, 9, 10, 11; Part D: Regulation 13; and Part G: Regulations 19 and 20, Chapter II-2 are applicable.
7 Review Procedures

7.1 Administration Review

When the vessel is issued a Passenger Ship Safety Certificate, Cargo Ship Safety Equipment Certificate or Cargo Ship Safety Construction Certificate by the flag Administration or its agent other than ABS, such Certificate will be accepted as evidence that the vessel is in accordance with the applicable criteria in 1974 SOLAS, as amended.

Where the Administration undertakes any part of the review and ABS is issuing the above Certificate, the acceptance by the Administration will be required before the certificate is issued.

Compliance with the Rule requirements, in addition to those in 1974 SOLAS, as amended, is to be verified by ABS.

7.3 ABS Review

In all other cases, the required information and plans are to be submitted to ABS for review.

9 The Review of Craft Constructed of Fiber Reinforced Plastic (FRP)

FRP fire-restricting divisions may be considered provided they meet the required tests for fire-restricting materials and fire-resisting divisions, or comply with an acceptable fire risk assessment. FRP divisions may also be considered on the basis of location with regard to diminished fire risk and enhanced fire detection/extinguishing means.

TABLE 1A Equipment for Self-propelled Ocean-going Craft.........276
TABLE 1B Equipment for Self-propelled Ocean-going Craft.........278
3  PART
5  CHAPTER  Equipment
1  SECTION  Anchoring and Mooring Equipment

1  General (1 July 2018)
All craft are to have a complete equipment set of anchor(s) and chains as outlined in this Section. The symbol Ⓖ, a condition of classification, placed after the symbols of classification in the Record, thus: ★A1Ⓔ, indicates that the equipment of the craft is in compliance with the requirements of these Rules, and tested in accordance with 3-5-1/7, or with requirements, which have been specially approved for the particular service. The following is an example:
★ A1Ⓔ, HSC, OE, ★AMS

Cables which are intended to form part of the equipment are not to be used as deck chains when the craft is launched. The inboard ends of the cables of the bower anchors are to be secured by efficient means (see 3-5-1/15). Anchors and their cables are to be connected and positioned, ready for use. Means are to be provided for stopping each cable as it is paid out, and the windlass is to be capable of heaving in either cable. Suitable arrangements are to be provided for securing the anchors and stowing the cables. See 3-5-1/16.

Equipment Number calculations for unconventional vessels with unique topside arrangements or operational profiles may be specially considered. Such consideration may include accounting for additional wind areas of widely separated deckhouses or superstructures in the equipment number calculations or equipment sizing based on direct calculations. However, in no case may direct calculations be used to reduce the equipment size to be less than that required by 3-5-1/3.

3  Calculation of EN

3.1  Monohulls (1 July 2018)
The basic Equipment Number (EN) is to be obtained from the following equation for use in determining required equipment.

\[ EN = k \Delta^{2/3} + m(Ba + \Sigma bh) + nA \]

where

\[
\begin{align*}
  k &= 1.0 (1.0, 1.012) \\
  m &= 2 (2, 0.186) \\
  n &= 0.1 (0.1, 0.00929) \\
  \Delta &= \text{molded displacement, in metric tons (long tons), at the summer load waterline.} \\
  B &= \text{molded breadth, as defined in 3-1-1/5, in m (ft)}
\end{align*}
\]
\[ h = \ \text{effective height, in m (ft), from the Summer Load waterline to the top of the uppermost house; for the lowest tier, } h \text{ is to be measured at centerline from the upper deck or from a notional deck line where there is local discontinuity in the upper deck, as shown in 3-5-1/Figure 1.} \]
\[ h_1, h_2, h_3 \ldots \] as shown in 3-5-1/3.1 FIGURE 1A. In the calculation of \( h \), sheer and trim may be neglected.

\[ a = \ \text{freeboard, in m (ft), from the light waterline amidships.} \]

\[ h_1, h_2, h_3 \ldots = \ \text{height, in m (ft), on the centerline of each tier of houses having a breadth greater than } B/4. \]

\[ A = \ \text{profile area, in } m^2 (ft^2), \text{ of the hull, superstructure and houses above the summer load waterline which are within } L \text{ (see 3-1-1/3). Superstructures or deckhouses having a breadth at any point no greater than } 0.25B \text{ may be excluded. Screens and bulwarks more than } 1.5 \text{ m (4.9 ft) in height are to be regarded as parts of houses when calculating } h \text{ and } A. \text{ The height of the hatch coamings and that of any deck cargo, such as containers, may be disregarded when determining } h \text{ and } A, \text{ except as specified by 3-5-1/17.3. With regard to determining } A, \text{ when a bulwark is more than } 1.5 \text{ m (4.9 ft) high, the area shown below as } A' \text{ should be included in } A. \]

\[ b = \ \text{breadth, in m (ft), of the widest superstructure or deckhouse on each tier.} \]
3.3 **Multi-Hulled Craft**

Anchors and chains are to be not less than given in 3-5-1/19.7 TABLE 1 and the numbers, weights and sizes of these are to be based on the equipment number obtained from the following equation. Special consideration will be given where anchoring and mooring conditions are specified.

\[
\text{Equipment Number} = 2k \left( \frac{\Delta}{2} \right)^{2/3} + m[(2Ba) + B_1(a_1 + \sum h)] + nA
\]

\(k, \Delta, m, n\) and \(A\) are defined in 3-5-1/3.1.

\(B, B_1, a, a_1, h_1, h_2, h_3, \sum h\) are shown in 3-5-1/3.3 FIGURE 1B.
5 Equipment, Weight and Size

The equipment, weight and size of all craft is to be in accordance with 3-5-1/19.7 TABLE 1, in association with the EN calculated in 3-5-1/3.

5.1 Alternatives for Anchor Size

The requirements for anchor sizing given in Appendix 3-5-A1 may be used in lieu of the anchor size and number given by 3-5-1/19.7 TABLE 1. The requirements in 3-5-1/9 are not applicable when the alternative anchor sizing requirements are used. Where one anchor is required by using the alternative arrangement, the total length of chain required is one-half the value given in 3-5-1/19.7 TABLE 1.

5.3 Wire Rope

Wire rope may be used in lieu of chain. The wire is to have a breaking strength not less than the grade 1 chain of required size and a length of at least 1.5 times the chain it is replacing. Between the wire rope and anchor, chain cable of the required size and having a length of 12.5 m (41.0 ft), or the distance between the anchor in the stored position and winch, whichever is less, is to be fitted.

5.5 Synthetic Fiber Rope

Synthetic fiber rope may be used in lieu of anchor chain cable provided the craft meets the following:

- The craft is less than 54 m (175 ft) in length.
- A length of chain is to be fitted between the anchor and synthetic fiber line.
- The chain is not to be less than the required Grade 1 chain for the equipment number.
iv) The chain length is to be at least the distance between the windlass and the anchor in the stowed position and not less than 0.2L meters (feet).

v) The ropes are to be stowed on drums or lockers, protected from the weather and sea, and are to be lead over rollers.

vi) The rope length is to be at least 1.5 times the required chain length.

vii) The breaking strength of the rope is to be at least equal to the breaking strength of the required Grade 1 chain cable.

viii) Synthetic fiber ropes for this application are to be polyamide fiber rope or equivalent. Polypropylene rope is not to be used.

ix) If the anchors are HHP or SHHP, the combined cable/synthetic rope is to be adequate for the verified holding power of the anchor.

5.7 Restricted Service Craft (2014)

Craft intended for restricted service (see 1-2-2/7) and having their own moorage are to have one anchor of the tabular weight and one-half the tabulated length of anchor chain as indicated in 3-5-1/19.7 TABLE 1. Alternatively, two anchors of one-half the tabular weight with the total length of anchor chain listed in 3-5-1/19.7 TABLE 1 may be fitted provided both anchors are positioned and ready for use and the windlass is capable of heaving in either anchor. These craft are to have adequate towing arrangements so that the craft can be towed in the worst intended conditions. In the areas of the towing arrangements where the towing cable is susceptible to chafing there is to be sufficient radius to prevent the cable from being damaged when under load.

7 Materials and Tests

Material and testing for anchors and chains on craft are to be in accordance with the requirements of Part 2, Chapter 2 for the respective sizes of anchors and chains. See Sections 2-2-1 and 2-2-2. Materials and tests for wire rope are to be in accordance with a national or other recognized standard.

9 Anchor Types

9.1 General

Anchors are in general to be of the stockless type. The weight of the head of a stockless anchor, including pins and fittings, is not to be less than three-fifths of the total weight of the anchor.

9.3 High Holding Power Anchors (HHP)

Where the anchor has a proven holding power of not less than two times that of an ordinary stockless anchor and has been tested in accordance with Section 2-2-1 a weight reduction of 25% from the weight specified in 3-5-1/19.7 TABLE 1 will be given. For HHP anchors an appropriate notation will be made in the Record.

9.5 Super High Holding Power Anchors (SHHP) (2019)

For craft intended for restricted service, provided the anchor has a proven holding power of not less than four times that of an ordinary stockless anchor and has been tested in accordance with Section 2-2-1, a weight reduction of 50% from the weight specified in 3-5-1/19.7 TABLE 1 will be given. For SHHP anchors an appropriate notation will be made in the Record.

11 Windlass Support Structure and Cable Stopper

11.1 General (2014)

The windlass is to be of good and substantial make suitable for the size of intended anchor cable. The winch is to be well bolted down to a substantial bed, and deck beams below the windlass are to be of extra
strength and additionally supported. Where wire ropes are used in lieu of chain cables, winches capable of controlling the wire rope at all times are to be fitted.

Construction and installation of all windlasses and winches used for anchoring are to be carried out in accordance with the following requirements, to the satisfaction of the Surveyor. In general, the design is to conform to an applicable standard or code of practice. As a minimum, standards or practices are to indicate strength, performance and testing criteria.

The manufacturer or builder is to submit in accordance with 4-1-1/7, the following, as applicable:

11.1.1 Plans
   i) Arrangement and details of the windlass or winch, drums, brakes, shaft, gears, coupling bolts, wildcat, sheaves, pulleys and foundation.
   ii) Electric one line diagram
   iii) Piping system diagrams
   iv) Control arrangements.

Plans or data are to show complete details including power ratings, working pressures, welding details, material specifications, pipe and electric cable specifications, etc.

11.1.2 Calculations
Detailed stress calculations for the applicable system components listed in 3-5-1/11.1.1.i above. The calculations are to be based on the breaking strength of the chain or wire rope; are to indicate maximum torque or load to which the unit will be subjected and also show compliance with either applicable sections of the Rules, such as Section 4-3-1 and Appendix 4-3-1-A1 for the gears and shafts, or to other recognized standard or code of practice.

11.3 Support Structure
The windlass is to be bolted down to a substantial foundation, which is to meet the following load cases and associated criteria.

An independent cable stopper and its components are to be adequate for the load imposed. The arrangements and details of the cable stopper are to be submitted for review.

11.3.1 Operating Loads
11.3.1(a) Load on Windlass Support Structure.
The following load is to be applied in the direction of the chain.

With cable stopper not attached to windlass: 45% of B.S.
With cable stopper attached to windlass: 80% of B.S.
Without cable stopper: 80% of B.S.

B.S. = minimum breaking strength of the chain, as indicated in 2-2-2/27 TABLE 2 and 2-2-2/27 TABLE 3 of the Rules for Materials and Welding (Part 2).

11.3.1(b) Load on Cable Stopper and Support Structure.
A load of 80% of B.S. is to be applied in the direction of the chain.

11.3.1(c) Allowable Stress (1 July 2018)
The stresses, based on gross thickness, in the structures supporting the windlass and cable stopper are not to exceed the following values:

- Normal stress: 100% of the specified minimum yield stress of the material
11.3.2 Sea Loads (2014)

For craft with length, $L$ (as defined in 3-1-1/3), over 80 meters (263 feet), where the height of the exposed deck in way of the item is less than $0.1L$ or 22 m above the summer load waterline, whichever is the lesser, the windlass supporting structures located on the exposed fore deck within the forward $0.25L$ are to meet the following requirements Where the mooring winch is integral with the windlass, it is to be considered as a part of the windlass for the purpose of said paragraph.

11.3.2(a) Pressures.
The following pressures and associated areas are to be applied (see 3-5-1/11.3.2(d) FIGURE 2):

- 200 kN/m$^2$ (20.4 tf/m$^2$, 4178 lbs/ft$^2$) normal to the shaft axis and away from the forward perpendicular, over the projected area in this direction,
- 150 kN/m$^2$ (15.3 tf/m$^2$, 3133 lbs/ft$^2$) parallel to the shaft axis and acting both inboard and outboard separately, over the multiple of $f$ times the projected area in this direction,

where $f$ is defined as:

$$f = 1 + \frac{B}{H}, \text{ but need not be taken as greater than 2.5}$$

$$B = \text{width of windlass measured parallel to the shaft axis}$$

$$H = \text{overall height of windlass}.$$

11.3.2(b) Forces.

Forces in the bolts, chocks and stoppers securing the windlass to the deck are to be calculated. The windlass is supported by $N$ groups of bolts, each containing one or more bolts, see 3-5-1/11.3.2(d) FIGURE 2.

i) **Axial Forces.** The aggregate axial force $R_i$ in respective group of bolts (or bolt) $i$, positive in tension, may be calculated from the following equations:

$$R_{xi} = P_x h x_i A_i / I_x$$

$$R_{yi} = P_y h y_i A_i / I_y$$

and

$$R_i = R_{xi} + R_{yi} - R_{si}$$

where

- $P_x = \text{force, kN (tf, lbs), acting normal to the shaft axis}$
- $P_y = \text{force, kN (tf, lbs), acting parallel to the shaft axis, either inboard or outboard, whichever gives the greater force in bolt group } i$\n- $h = \text{shaft height above the windlass mounting, cm (in.)}$
- $x_i y_i = x$ and $y$ coordinates of bolt group $i$ from the centroid of all $N$ bolt groups, positive in the direction opposite to that of the applied force, cm (in.)
- $A_i = \text{cross sectional area of all bolts in group } i, \text{ cm}^2 \text{ (in}^2)$
- $I_x = A_i x_i^2 \text{ for } N \text{ bolt groups}$
\[ I_y = A_i y_i^2 \] for \( N \) bolt groups

\[ R_{si} = \text{static reaction at bolt group } i, \text{ due to weight of windlass.} \]

\textit{ii) Shear forces.} Aggregated shear forces, \( F_{xi}, F_{yi} \), applied to the respective bolt group, \( i \), of bolts, and the resultant combined force, \( F_i \), may be calculated from:

\[ F_{xi} = \frac{P_x - \alpha g M}{N} \]

\[ F_{yi} = \frac{P_y - \alpha g M}{N} \]

and

\[ F_i = \left( F_{xi}^2 + F_{yi}^2 \right)^{0.5} \]

where

\[ \alpha = \text{coefficient of friction (0.5)} \]

\[ M = \text{mass of windlass, in tonnes (Ltons)} \]

\[ g = \text{gravity: } 9.81 \text{ m/sec}^2 (32.2 \text{ ft/sec}^2) \]

\[ N = \text{number of groups of bolt.} \]

The axial tensile/compressive and lateral forces from the above equations are also to be considered in the design of the supporting structure.

\textit{11.3.2(c) Stresses in Bolts.}

Tensile axial stresses in the individual bolts in each group of bolts, \( i \), are to be calculated. The horizontal forces, \( F_{xi} \) and \( F_{yi} \), are normally to be reacted by shear chocks. Where “fitted” bolts are designed to support these shear forces in one or both directions, the von Mises equivalent stresses in the individual “fitted” bolts are to be calculated, and compared to the stress under proof load. Where pour-able resins are incorporated in the holding down arrangements, due account is to be taken in the calculations.

\textit{11.3.2(d) Allowable Stress. (1 July 2018)}

\textit{i) Bolts.} The safety factor against bolt proof strength is to be not less than 2.0.

\textit{ii) Supporting Structures.} The stresses in the above deck framing and the hull structure supporting the windlass are not to exceed the following value.

- Normal Stress: 100% of the yield strength of the material
- Shear Stress: 60% of the yield strength of the material
FIGURE 2
Direction of Forces and Weight

Note:
P_y to be examined from both inboard and outboard directions separately - see 3-5-1/11.3.2(2). The sign convention for y is reversed when P_y is from the opposite direction as shown.

FIGURE 3
Sign Convention

Coordinates x and y are shown as either positive (+ve) or negative (-ve).
11.5 **Craft Less Than 61 m (200 ft) in Length**

Where it is not practical to fit an anchor windlass or winch that has been approved by ABS in accordance with 3-5-1/11.1, consideration will be given to fitting an anchor windlass that is provided with a certificate from the manufacturer. This certificate is to state that the equipment has been designed to accommodate the breaking strength of the required chain or wire rope. If the required anchor weight is less than 38.5 kg (85 lbs) no winch or windlass is required.

13 **Trial**

See 3-7-2/1.

14 **Hawse Pipes**

Hawse pipes are to be of ample size and strength; they are to have full rounded flanges and the least possible lead, in order to minimize the nip on the cables; they are to be securely attached to thick doubling or insert plates by continuous welds the size of which are to be in accordance with Section 3-2-13 for the plating thickness and type of joint selected. When in position they are to be thoroughly tested for watertightness by means of a hose in which the water pressure is not to be less than 2.06 bar (2.1 kgf/cm², 30 psi). Hawse pipes for stockless anchors are to provide ample clearances; the anchors are to be shipped and unshipped so that the Surveyor may be satisfied that there is no risk of the anchor jamming in the hawse pipe. Care is to be taken to ensure a fair lead for the chain from the windlass to the hawse pipes and to the chain pipes.

15 **Securing of the Inboard Ends of Chain Cables (1 July 2018)**

Arrangements are to be provided for securing the inboard ends of the bower anchor chain cables. The chain cables are to be secured to structures by a fastening able to withstand a force not less than 15% nor more than 30% of the breaking load of the chain cable. The fastening is to be provided with a mean suitable to permit, in case of emergency, an easy slipping of the chain cables to sea, operable from an accessible position outside the chain locker.

16 **Securing of Stowed Anchors (1 July 2018)**

Arrangements are to be provided for securing the anchors and stowing the cables. To hold the anchor tight in against the hull or the anchor pocket, respectively, anchor lashings (e.g., a “devil’s claw”) are to be fitted. Anchor lashings are to be designed to resist a load at least corresponding to twice the anchor mass plus 10 m (32.8 ft) of cable without exceeding 40% of the yield strength of the material.

17 **Mooring and Towing Equipment (1 July 2018)**

17.1 **All Craft (1 July 2018)**

Hawsers, towlines and requirements for associated equipment and arrangements as described in 3-5-1/17.9 and 3-5-1/17.11 are not required as a condition of classification. The hawsers and towlines listed in 3-5-1/19.7 TABLE 2 and 3-5-1/19.7 TABLE 3 are intended as a minimum guide.

17.3 **Mooring Lines (1 July 2018)**

The mooring lines for craft with Equipment Number EN of less than or equal to 2000 are given in 3-5-1/17.3.1. For other craft, the mooring lines are given in 3-5-1/17.3.2.

The Equipment Number EN is to be calculated in compliance with 3-5-1/3. Deck cargo as given by the loading manual should be included for the determination of side-projected area \( A \).

17.3.1 **Mooring Lines for Craft with EN ≤ 2000**

The minimum mooring lines for craft having an Equipment Number EN of less than or equal to 2000 are given in 3-5-1/19.7 TABLE 2 is intended as a guide.
For craft having an $A/EN$ ratio greater than 0.9 for SI or MKS units (9.7 for US units), the number of hawsers given in 3-5-1/19.7 TABLE 2 is to be increased by the number given below:

<table>
<thead>
<tr>
<th>$A/EN$ Ratio</th>
<th>Increase number of hawsers by</th>
</tr>
</thead>
<tbody>
<tr>
<td>SI Units MKS Units</td>
<td>U.S. Units</td>
</tr>
<tr>
<td>Above 0.9 up to 1.1</td>
<td>above 9.7 up to 11.8</td>
</tr>
<tr>
<td>Above 1.1 up to 1.2</td>
<td>above 11.8 up to 12.9</td>
</tr>
<tr>
<td>above 1.2</td>
<td>above 12.9</td>
</tr>
</tbody>
</table>

17.3.2 Mooring Lines for Craft with $EN > 2000$

The minimum strength and number of mooring lines for craft with an Equipment Number $EN > 2000$ are given in 3-5-1/17.3.2(a) and 3-5-1/17.3.2(b), respectively, and is intended as a guide. The length of mooring lines is given by 3-5-1/17.3.3.

The strength of mooring lines and the number of head, stern, and breast lines (see Note below defining head, stern, and breast lines) for craft with an Equipment Number $EN > 2000$ are based on the side-projected area $A_1$. Side projected area $A_1$ should be calculated similar to the side-projected area $A$ according to 3-5-1/3 but considering the following conditions:

- The lightest draft of usual loading conditions is to be considered if the ratio of the freeboard in the lightest draft and the full load condition is equal to or above two. Usual loading conditions are loading conditions as given by the trim and stability booklet that are expected to regularly occur during operation and, in particular, that exclude light weight conditions, propeller inspection conditions, etc.

- Wind shielding of the pier may be considered for the calculation of the side-projected area $A_1$ unless the craft is intended to be regularly moored to jetty type piers. A height of the pier surface of 3 m (9.8 ft) over waterline may be assumed (i.e., the lower part of the side-projected area with a height of 3 m (9.8 ft) above the waterline) for the considered loading condition and may be disregarded for the calculation of the side-projected area $A_1$.

- Deck cargo as given by the loading manual is to be included for the determination of side-projected area $A_1$. Deck cargo may not need to be considered if a usual light draft condition without cargo on deck generates a larger side-projected area $A_1$ than the full load condition with cargo on deck. The larger of both side-projected areas is to be chosen as side-projected area $A_1$.

The mooring lines as given here under are based on a maximum current speed of 1.0 m/s (3.3 ft/s) and the following maximum wind speed $v_w$, in m/s (ft/s):

$$v_w = 25.0 - 0.002(A_1 - 2000) \text{ m/s}$$

for passenger craft, ferries, and car carriers with $2000 \text{ m}^2 < A_1 \leq 4000 \text{ m}^2$

$$v_w = 21.0 \text{ m/s}$$

for passenger craft, ferries, and car carriers with $A_1 > 4000 \text{ m}^2$

$$v_w = 25.0 \text{ m/s}$$

for other craft

$$v_w = 82.0 - 0.00061(A_1 - 21528) \text{ ft/s}$$

for passenger craft, ferries, and car carriers with $21528 \text{ ft}^2 < A_1 \leq 43056 \text{ ft}^2$

$$v_w = 68.9 \text{ ft/s}$$

for passenger craft, ferries, and car carriers with $A_1 > 43056 \text{ ft}^2$

$$v_w = 82.0 \text{ ft/s}$$

for other craft
The wind speed is considered representative of a 30 second mean speed from any direction and at a height of 10 m (32.8 ft) above the ground. The current speed is considered representative of the maximum current speed acting on bow or stern (±10°) and at a depth of one-half of the mean draft. Furthermore, it is considered that craft are moored to solid piers that provide shielding against cross current.

Additional loads caused by, e.g., higher wind or current speeds, cross currents, additional wave loads, or reduced shielding from non-solid piers may need to be particularly considered. Furthermore, it should be observed that unbeneficial mooring layouts can considerably increase the loads on single mooring lines.

Notes:
The following is defined with respect to the purpose of mooring lines, see also figure below:

- Breast line: A mooring line that is deployed perpendicular to the craft, restraining the craft in the off-berth direction.
- Spring line: A mooring line that is deployed almost parallel to the craft, restraining the craft in the fore or aft direction.
- Head/Stern line: A mooring line that is oriented between longitudinal and transverse direction, restraining the craft in the off-berth and in fore or aft direction. The amount of restraint in the fore or aft and off-berth directions depends on the line angle relative to these directions.

17.3.2(a) Minimum Breaking Strength
The minimum breaking strength, in kN (kgf, lbf), of the mooring lines should be taken as:

$MBL = 0.1 A_1 + 350$ kN
$MBL = 10.20 A_1 + 35690$ kgf
$MBL = 2.089 A_1 + 78680$ lbf

The minimum breaking strength may be limited to 1275 kN (130,000 kgf, 286,600 lbf). However, in this case the moorings are to be considered as not sufficient for environmental conditions given by 3-5-1/17.3.2. For these craft, the acceptable wind speed $v_w^*$, in m/s, can be estimated as follows:

$MBL^* \geq \left( \frac{21}{v_w} \right)^2 \cdot MBL$ for $v_w$ in m/s
$MBL^* \geq \left( \frac{68.9}{v_w} \right)^2 \cdot MBL$ for $v_w$ in ft/s

where $v_w$ is the wind speed as per 3-5-1/17.3.2, $MBL^*$ the breaking strength of the mooring lines intended to be supplied and $MBL$ the breaking strength according to the above formula. However, the minimum breaking strength should not be taken less than corresponding to an acceptable wind speed of 21 m/s (68.9 ft/s).
If lines are intended to be supplied for an acceptable wind speed $v_w^*$ higher than $v_w$ as per 3-5-1/17.3.2, the minimum breaking strength should be taken as:

$$MBL^* = \left(\frac{v_w^*}{v_w}\right)^2 \cdot MBL$$

17.3.2(b) Number of Mooring Lines

The total number of head, stern, and breast lines (see Note in 3-5-1/17.3.2) should be taken as:

$$n = 8.3 \cdot 10^{-4} \cdot A_1 + 6 \quad \text{for } A_1 \text{ in } m^2$$

$$n = 7.71 \cdot 10^{-5} \cdot A_1 + 6 \quad \text{for } A_1 \text{ in } ft^2$$

For oil tankers, chemical tankers, bulk carriers, and ore carriers the total number of head, stern, and breast lines should be taken as:

$$n = 8.3 \cdot 10^{-4} \cdot A_1 + 4 \quad \text{for } A_1 \text{ in } m^2$$

$$n = 7.71 \cdot 10^{-5} \cdot A_1 + 4 \quad \text{for } A_1 \text{ in } ft^2$$

The total number of head, stern, and breast lines should be rounded to the nearest whole number.

The number of head, stern, and breast lines may be increased or decreased in conjunction with an adjustment to the strength of the lines. The adjusted strength, $MBL^*$, should be taken as:

$$MBL^* = 1.2 \cdot MBL \cdot \frac{n}{n^*} \leq MBL \quad \text{for increased number of lines}$$

$$MBL^* = MBL \cdot \frac{n}{n^*} \quad \text{for reduced number of lines}$$

where $n^*$ is the increased or decreased total number of head, stern and breast lines and $n$ the number of lines for the considered craft type as calculated by the above formulas without rounding.

Similarly, the strength of head, stern, and breast lines may be increased or decreased in conjunction with an adjustment to the number of lines.

The total number of spring lines (see Note in 3-5-1/17.3.2) is not to be taken as less than:

- Two lines, where $EN < 5000$
- Four lines, where $EN \geq 5000$

The strength of spring lines is to be the same as that of the head, stern, and breast lines. If the number of head, stern, and breast lines is increased in conjunction with an adjustment to the strength of the lines, the number of spring lines is to be likewise increased, but rounded up to the nearest even number.

17.3.3 Length of Mooring Lines

The length of mooring lines for craft with $EN$ of less than or equal to 2000 may be taken from 3-5-1/19.7 TABLE 2. For craft with $EN > 2000$ the length of mooring lines may be taken as 200 m (109 fathoms).

The lengths of individual mooring lines may be reduced by up to 7% of the above given lengths, but the total length of mooring lines should not be less than would have resulted had all lines been of equal length.
17.5 **Tow Line (1 July 2018)**

The tow lines are given in 3-5-1/19.7 TABLE 3 and are intended as a craft’s own tow line of a craft being towed by a tug or other craft. For the selection of the tow line from 3-5-1/19.7 TABLE 3, the Equipment Number (EN) is to be taken according to 3-5-1/3.

17.7 **Mooring and Tow Line Construction (1 July 2018)**

Tow lines and mooring lines may be of wire, natural fiber, or synthetic fiber construction or of a mixture of wire and fiber. For synthetic fiber ropes it is recommended to use lines with reduced risk of recoil (snap-back) to mitigate the risk of injuries or fatalities in the case of breaking mooring lines.

Notwithstanding the requirements given in 3-5-1/17.3 and 3-5-1/17.5, no fiber rope is to be less than 20 mm (0.79 in) in diameter. For polyamide ropes, the minimum breaking strength is to be increased by 20% and for other synthetic ropes by 10% to account for strength loss due to, among others, aging and wear.

17.9 **Mooring Winches (1 July 2018)**

17.9.1 Each winch is to be fitted with brakes with a holding capacity sufficient to prevent unreeling of the mooring line when the rope tension is equal to 80% of the minimum breaking strength of the rope as fitted on the first layer. The winch is to be fitted with brakes that will allow for the reliable setting of the brake rendering load.

17.9.2 For powered winches the maximum hauling tension which can be applied to the mooring line (the reeled first layer) is not be less than 1/4.5 times, nor be more than 1/3 times the rope's minimum breaking strength. For automatic winches, these figures apply when the winch is set to the maximum power with automatic control.

17.9.3 For powered winches on automatic control, the rendering tension that the winch can exert on the mooring line (the reeled first layer) is not to exceed 1.5 times, nor be less than 1.05 times the hauling tension for that particular power setting of the winch. The winch is to be marked with the range of rope strength for which it is designed.

17.11 **Mooring and Towing Arrangement (1 July 2018)**

17.11.1 Mooring Arrangement

Mooring lines in the same service (e.g., breast lines, see Note in 3-5-1/17.11.2) should be of the same characteristic in terms of strength and elasticity.

As far as possible, a sufficient number of mooring winches are to be fitted to allow for all mooring lines to be belayed on winches. This allows for an efficient distribution of the load to all mooring lines in the same service and for the mooring lines to shed load before they break. If the mooring arrangement is designed such that mooring lines are partly to be belayed on bitts or bollards, these lines are considered to be not as effective as the mooring lines belayed on winches.

Mooring lines are to have a lead as straight as is practicable from the mooring drum to the fairlead.

At points of change in direction, sufficiently large radii of the contact surface of a rope on a fitting are to be provided to minimize the wear experienced by mooring lines and as recommended by the rope manufacturer for the rope type intended to be used.

17.11.2 Towing Arrangement

Towing lines, in general, should be led through a closed chock. The use of open fairleads with rollers or closed roller fairleads is to be avoided.
For towing purposes, at least one chock is to be provided close to centerline of the craft forward and aft. It is also beneficial to provide additional chocks on port and starboard side at the transom and at the bow.

Towing lines are to have a straight lead from the towing bitt or bollard to the chock.

For the purpose of towing, bitts or bollards serving a chock are to be located slightly offset and, as far as practicable, a distance of at least 2 m (6.6 ft) away from the chock, see figure below:

As far as practicable, warping drums are to be positioned not more than 20 m (65.6 ft) away from the chock, measured along the path of the line.

Attention is to be given to the arrangement of the equipment for towing and mooring operations in order to prevent interference of mooring and towing lines as far as practicable. It is beneficial to provide dedicated towing arrangements separate from the mooring equipment.

For all craft, it is recommended to provide towing arrangements fore and aft of sufficient strength for ‘other towing’ service as defined in 3-2-7/4.3.2 of the Marine Vessel Rules.

19  Bollard, Fairlead and Chocks

19.1 General
The arrangements and details below are for guidance only and are not required for class. The guidance for the supporting structures of these deck fittings are specified in 3-2-7/4 of the Marine Vessel Rules.

19.3 Shipboard Fittings (1 July 2018)
The size of shipboard fittings is to be in accordance with recognized standards (e.g. ISO 13795 Ships and marine technology – Ship’s mooring and towing fittings – Welded steel bollards for sea-going vessels) or comply with the requirements given in 3-5-1/19.3.1 and 3-5-1/19.3.2. For shipboard fittings not in accordance with recognized standard the corrosion addition, \( t_c \), and the wear allowance, \( t_w \), given in 3-2-7/4.7 of the Marine Vessel Rules, respectively, are to be considered. The design load used to assess shipboard fittings and their attachments to the hull are to be in accordance with the requirements as specified in 3-2-7/4 of the Marine Vessel Rules.

19.3.1 Mooring Operations (1 July 2018)
Shipboard fittings may be selected from a recognized national or international standard. The Safe Working Load (SWL) is to be suitable for mooring lines with a minimum breaking strength that is not less than that according to 3-5-1/19.7 TABLE 2 (see Notes in 3-2-7/4.3.1 of the Marine Vessel Rules).
Mooring bitts (double bollards) are to be chosen for the mooring line attached in figure-of-eight fashion if the industry standard distinguishes between different methods to attach the line, i.e. figure-of-eight or eye splice attachment.

When the shipboard fitting is not selected from an accepted industry standard, the strength of the fitting and of its attachment to the craft is to be in accordance with requirements related to mooring in 3-2-7/4.3 and 3-2-7/4.5 of the Marine Vessel Rules. Mooring bitts (double bollards) are required to resist the loads caused by the mooring line attached in figure-of-eight fashion, see Note. For strength assessment beam theory or finite element analysis using net scantlings is to be applied, as appropriate. Corrosion additions are to be as defined in 3-2-7/4.7.2 of the Marine Vessel Rules. A wear down allowance is to be included as defined in 3-2-7/4.7.3 of the Marine Vessel Rules. Consideration may be given to accepting load tests as alternative to strength assessment by calculations.

Note: With the line attached to a mooring bitt in the usual way (figure-of-eight fashion), either of the two posts of the mooring bitt can be subjected to a force twice as large as that acting on the mooring line. Disregarding this effect, depending on the applied industry standard and fitting size, overload may occur.

19.3.2 Towing Operations (1 July 2018)

Shipboard fittings may be selected from a recognized industry standard and are to be at least based on the following loads:

i) For normal towing operations, the intended maximum towing load (e.g., static bollard pull) as indicated on the towing and mooring arrangements plan

ii) For other towing service, the minimum breaking strength of the tow line according to 3-5-1/19.7 TABLE 3 (see Notes in 3-2-7/4.3.2 for other towing services)

iii) For fittings intended to be used for, both, normal and other towing operations, the greater of the loads according to i) and ii)

Towing bitts (double bollards) may be chosen for the towing line attached with eye splice if the industry standard distinguishes between different methods to attach the line, i.e. figure-of-eight or eye splice attachment.

When the shipboard fitting is not selected from an accepted industry standard, the strength of the fitting and of its attachment to the craft is to be in accordance with requirements related to towing in 3-2-7/4.3 and 3-2-7/4.5 of the Marine Vessel Rules. Towing bitts (double bollards) are required to resist the loads caused by the towing line attached with eye splice. For strength assessment beam theory or finite element analysis using net scantlings is to be applied, as appropriate. Corrosion additions are to be as defined in 3-2-7/4.7.2 of the Marine Vessel Rules. A wear down allowance is to be included as defined in 3-2-7/4.7.3 of the Marine Vessel Rules. Consideration may be given to accepting load tests as alternative to strength assessment by calculations.

19.5 Safe Working Load (SWL) and Towing Load (TOW) (1 July 2018)

The requirements on SWL apply for a single post basis (no more than one turn of one cable).

19.5.1 Mooring Operations (1 July 2018)

i) The Safe Working Load (SWL) is the load limit for mooring purpose.

ii) Unless a greater SWL is requested by the applicant according to 3-2-7/4.3.3 of the Marine Vessel Rules, the SWL is not to exceed the minimum breaking strength of the mooring line according to 3-5-1/19.7 TABLE 2, see Notes in 3-2-7/4.3.1 of the Marine Vessel Rules.

iii) The SWL, in tonnes, of each shipboard fitting is to be marked (by weld bead or equivalent) on the fittings used for mooring. For fittings intended to be used for both
mooring and towing, TOW, in tonnes, according to 3-5-1/19.5.2 is to be marked in addition to SWL.

iv) The above requirements on SWL apply for the use with no more than one mooring line.

v) The towing and mooring arrangements plan mentioned in 3-5-1/19.7 is to define the method of use of mooring lines.

19.5.2 Towing Operations (1 July 2018)

i) The Safe Towing Load (TOW) is the load limit for towing purpose.

ii) TOW used for normal towing operations is not to exceed 80% of the design load per 3-2-7/4.3.2 of the Marine Vessel Rules for normal towing operations.

iii) TOW used for other towing operations is not to exceed 80% of the design load according to 3-2-7/4.3.2 of the Marine Vessel Rules for other towing service.

iv) For fittings used for both normal and other towing operations, the greater of the safe towing loads according to ii) and iii) is to be used.

v) For fittings intended to be used for both towing and mooring, the requirements in 3-2-7/4 of the Marine Vessel Rules and 3-5-1/19 applicable to mooring are to be applied relative to mooring operations.

vi) TOW, in tonnes, of each shipboard fitting is to be marked (by weld bead or equivalent) on the fittings used for towing. For fittings intended to be used for both towing and mooring, SWL, in tonnes, according to 3-5-1/19.5.1 is to be marked in addition to TOW.

vii) The above requirements on TOW apply for the use with no more than one line. If not otherwise chosen, for towing bitts (double bollards) TOW is the load limit for a towing line attached with eye-splice.

viii) The towing and mooring arrangements plan mentioned in 3-5-1/19.7 is to define the method of use of towing lines.

19.5.3 Marking and Plan

19.5.3(a) Marking. (1 July 2018)

The SWL of each shipboard fitting is to be marked (by weld bead or equivalent) on the fittings used for towing/mooring.

19.5.3(b) Plan.

The towing and mooring arrangements plan mentioned in 3-5-1/19.7 is to define the method of use of mooring lines and/or towing lines.

19.7 Towing and Mooring Arrangements Plan (1 July 2018)

The SWL and TOW for the intended use for each shipboard fitting is to be noted in the towing and mooring arrangements plan available on board for the guidance of the Master.

Information provided on the plan is to include in respect of each shipboard fitting:

- Location on the craft
- Fitting type
- SWL and TOW
- Purpose (mooring/harbor towing/other towing)
- Manner of applying towing or mooring line load including limiting fleet angles.

The above information is to be incorporated into the pilot card in order to provide the pilot proper information on harbor/other towing operations.
In addition, the towing and mooring arrangement plan is to include the following general information:

- the arrangement of mooring lines showing number of lines (N)
- the minimum breaking strength of each mooring line (MBL)
- the acceptable environmental conditions as given in 3-5-1/17.3.2 for the recommended minimum breaking strength of mooring lines for vessels with Equipment Number \( EN > 2000 \):
  - 30 second mean wind speed from any direction (\( v_w \) or \( v_w^* \) according to 3-5-1/17.3.2)
  - Maximum current speed acting on bow or stern (±10°)

**SI, MKS Units**

The weight per anchor of bower anchors given in 3-5-1/19.7 TABLE 1 is for anchors of equal weight. The weight of individual anchors may vary ±7% plus or minus from the tabular weight provided that the combined weight of all anchors is not less than that required for anchors of equal weight. The total length of chain required to be carried on board, as given in 3-5-1/19.7 TABLE 1, is to be reasonably divided between the two bower anchors.

ABS RULES FOR BUILDING AND CLASSING HIGH SPEED CRAFT • 2019

Page 277
### TABLE 1B

**Equipment for Self-propelled Ocean-going Craft (1 July 2018)**

**US Units**

The weight per anchor of bower anchors given in 3-5-1/19.7 TABLE 1 is for anchors of equal weight. The weight of individual anchors may vary 7% plus or minus from the tabular weight, provided that the combined weight of all anchors is not less than that required for anchors of equal weight. The total length of chain required to be carried onboard, as given in 3-5-1/19.7 TABLE 1, is to be reasonably divided between the two bower anchors.

CHAPTER 5  Equipment

APPENDIX 1  Alternative Standard for the Required Anchor Size

1  General

All craft are to have anchor and chain that comply with the requirements in Section 3-5-1 of these Rules or the requirements listed below. The letter ⓒ will signify that the equipment of the craft is in compliance with the requirements in these Rules and tested in accordance with 3-5-1/9 of these Rules.

3  Anchor Size Requirement

A minimum of one (1) anchor is to be provided that has a holding power in a bottom that has an average consistency between mud and sand that is greater than determined by the following equation. The holding power of the anchor is to be certified by the anchor manufacturer.

\[
HP = 0.0195AV_w^2 + 0.114\sqrt{\Delta L(V_c)}^{1.825} + 7.74N_pA_pV_c^2 \quad \text{kg}
\]

\[
HP = 0.004AV_w^2 + 0.14\sqrt{\Delta L(V_c)}^{1.825} + 1.59N_pA_pV_c^2 \quad \text{lbf}
\]

where

- \(HP\) = required holding power of anchor, in kg (lbf)
- \(A\) = projected frontal area of the craft above the waterline, in m\(^2\) (ft\(^2\))
- \(V_w\) = velocity of wind acting on the craft, not to be taken less than 50 knots
- \(\Delta\) = molded displacement of the craft, in mt (lbf), to the summer load line
- \(L\) = length of craft, in m (ft), as defined in 3-1-1/3
- \(V_c\) = velocity of current acting on the craft, not to be taken less than 3 knots
- \(N_p\) = number of propellers fitted on the craft
- \(A_p\) = area of one propeller, in m\(^2\) (ft\(^2\))

5  Anchor Chain, Cable, or Rope

The required size and length of chain, cable, or rope is to be as indicated in Section 3-5-1. Where one anchor is allowed the required chain length is one half the length required from 3-5-1/Table 1.

CHAPTER 6  Navigation

SECTION 1  Visibility

1  Navigation Bridge Visibility

All craft of not less than 55 m (180 ft) in length overall having the keel laid or in similar stage of construction on or after 1 July 1998 are to meet the following requirements with regard to the visibility from the navigation bridge, unless they are navigating solely the Great Lakes of North America and their connecting and tributary waters as far east as the lower exit of the St. Lambert Lock at Montreal in the Province of Quebec, Canada. Special consideration will be given to craft that operate only on domestic or on short, limited, international voyages.

1.1  Field of Vision

1.1.1  Conning Position

1.1.1(a)  The view of the sea surface from the conning position is not to be obscured by more than $2L_{OA}$ (Length Overall) or 500 m (1640 ft), whichever is less, forward of the bow to 10° on either side for all conditions of draft, trim and deck cargo under which the particular craft is expected to operate. See 3-6-1/1.1.1(a) FIGURE 1.

1.1.1(b)  No blind sector caused by cargo, cargo gear or other obstructions outside of the wheelhouse forward of the beam which obstructs the view of the sea surface as seen from the conning position is to exceed 10°. The total arc of blind sectors is not to exceed 20°. The clear sectors between blind sectors are to be at least 5°. However, in the view described in 3-6-1/1.1.1(a), each individual blind sector is not to exceed 5°.

1.1.1(c)  The horizontal field of vision from the conning position is to extend over an arc of not less than 225°, that is, from right ahead to not less than 22.5° abaft the beam on either side of the craft. See 3-6-1/1.1.3 FIGURE 3.
1.1.2 Bridge Wing

1.1.2(a)
From each bridge wing, the horizontal field of vision is to extend over an arc of at least 225°, that is, from at least 45° on the opposite bow to right ahead and then from right ahead to right astern through 180° on the same side of the craft. See 3-6-1/1.1.3 FIGURE 4.

1.1.2(b)
The craft’s side is to be visible from the bridge wing.

i) The requirements of 3-6-1/1.1.2(b) are accomplished when:

- A view from the bridge wing plus a distance corresponding to a reasonable and safe distance of a seafarer leaning over the side of the bridge wing, which needs not to be more than 400 mm (16 in.), to the location vertically right under the maximum beam of the ship at the lowest seagoing draft is not obscured; or
- The sea surface at the lowest seagoing draft and with a transverse distance of 500 mm (19.5 in.) and more from the maximum beam throughout the ship’s length is visible from the side of the bridge wing.

See 3-6-1/1.1.2(b) FIGURE 2.

ii) For particular ship types, such as tug/tow boat, offshore supply vessel (OSV), rescue ship, work ship (e.g., floating crane ships), etc., that are designed such that, in normal operations, they come along side, or operate in close proximity to, other vessels or offshore structures at sea, 3-6-1/1.1.2(b) is met provided the bridge wings extend at least to a location from which the sea surface, at the lowest seagoing draft and at a transverse distance of 1500 mm (59 in.) from the maximum beam throughout the ship’s length, is visible. If this ship type is changed to a type other than those addressed in this paragraph, then the interpretation in this paragraph would no longer apply.
1.1.3 Main Steering Position

From the main steering position, the horizontal field of vision is to extend over an arc from right ahead to at least 60° on each side of the craft. See 3-6-1/1.1.3 FIGURE 5.

FIGURE 3
FIGURE 4

FIGURE 5 (2017)
1.1.4 Remote Camera System (1 July 2014)
For craft of 55 m (180 ft) in length, and above, the use of a remote camera system may be accepted for ships of unconventional design, other than those mentioned in 3-6-1/1.1.2(b).ii. above, as means for achieving the view of the craft’s side from the bridge wing, provided:

i) The installed remote camera system is to be redundant from the circuit breaker to the camera and screen, including communication cables, i.e. the system is to provide on each side of the craft redundancy of:
   - The power cables and circuit breakers from the main switchboard to the camera and the screen;
   - The camera;
   - The screen;
   - The transmission lines from the camera to the display screen; and
   - The components associated with these lines and cables;

ii) The remote camera system is powered from the craft’s main source of electrical power and is not required to be powered by the emergency source of electrical power;

iii) The remote camera system is capable of continuous operation under environmental conditions as per 4-7-9/15.5 TABLE 9 and 4-7-9/15.5 TABLE 10;

iv) The view provided by the remote camera system is analogous to that from the bridge wing so the craft’s side is to be visible, and is also displayed at locations where the maneuvering of the craft may take place;

v) The upper edge of the craft’s side abeam is directly visible from locations where the maneuvering of the craft may take place.

1.3 Windows and Their Arrangements
Windows and their arrangements are to meet the following requirements:

1.3.1 Framing
Framing between navigation bridge windows is to be kept to a minimum to meet the structural strength and stiffness requirements, and is not to be installed immediately in front of any workstations.

1.3.2 Inclination Angle
The bridge front windows are to be inclined from a vertical plane top out, at an angle of not less than 10° and not more than 25°, see 3-6-1/1.3.2 FIGURE 6.
1.3.3 Glass
Polarized and tinted windows are not to be fitted.

1.3.4 Clear View
At all times, regardless of the weather conditions, at least two of the navigation bridge front windows are to provide a clear view, and in addition, depending on the bridge configuration, an additional number of windows are to provide a clear view. To this end, the following, or equivalent, is to be provided:

1.3.4(a) Sun Screens.
Sunscreens with minimum color distortion. These sunscreens are to be readily removable and not permanently installed.

1.3.4(b) Wipers and Fresh Water Wash Systems.
Heavy-duty wipers, preferably provided with an interval function, and fresh water wash systems. These wipers are to be capable of operating independently of each other.

1.3.4(c) De-icing and De-misting Systems.
De-icing and de-misting systems to be provided.

1.3.4(d) Fixed Catwalk.
A fixed catwalk with guardrails, fitted forward of the bridge windows, to enable manual cleaning of windows in the event of failure of the above systems.
1.3.5 Lower Edge
The height of the lower edge of the navigation bridge front windows above the bridge deck is to be kept as low as possible. In no case is the lower edge to present an obstruction to the forward view as described in this Section.

1.3.6 Upper Edge
The upper edge of the navigation bridge front windows is to allow a forward view of the horizon for a person with a height of eye of 1800 mm (5 ft-11 in.) above the bridge deck at the conning position when the craft is pitching in heavy seas. ABS, if satisfied that an 1800 mm (5 ft-11 in.) height of eye is unreasonable and impractical, may allow reduction of the height of eye, but not to less than 1600 mm (5 ft-3 in.). See 3-6-1/1.3.2 FIGURE 6.

1.5 Unconventional Design
For craft of unconventional design which cannot comply with the above requirements, arrangements are to be provided to the satisfaction of ABS to achieve a level of visibility that is as near as practical to those prescribed in this Section.

CHAPTER 7  Testing, Trials and Surveys During Construction – Hull

SECTION 1  Tank, Bulkhead and Rudder Tightness Testing (2018)

1  General

Testing to confirm the watertightness of tanks and watertight boundaries and the structural adequacy of tanks which form the watertight subdivisions(1) of craft is to be completed. Verification of the weathertightness of structures and shipboard outfitting is to be carried out. The tightness of all tanks and tight boundaries of new craft and those tanks and boundaries whose structural integrity is affected by major conversions or major repairs(2) is to be confirmed prior to the delivery of the craft or prior to the completion of the modification or repair as relevant.

Testing procedures of watertight compartments for craft built in compliance with SOLAS 1974 as amended are to be carried out in accordance with 3-7-1/3, unless:

i) The shipyard provides documentary evidence of the Owner’s agreement to a request to the flag Administration for an exemption from the application of Chapter II-1, Regulation 11 of SOLAS 1974 as amended, or for an equivalency agreeing that the content of 3-7-1/5 is equivalent to Chapter II-1, Regulation 11 of SOLAS 1974 as amended; and

ii) The above-mentioned exemption/equivalency has been granted by the responsible Flag Administration.

Testing procedures of watertight compartments are to be carried out in accordance with 3-7-1/5 for craft not built in compliance with SOLAS 1974 as amended and those craft built in compliance with SOLAS 1974 as amended for which:

i) The shipyard provides documentary evidence of the Owner’s agreement to a request to the Flag Administration for an exemption from the application of Chapter II-1, Regulation 11 of SOLAS 1974 as amended, or for an equivalency agreeing that the content of 3-7-1/5 is equivalent to Chapter II-1, Regulation 11 of SOLAS 1974 as amended; and

ii) The above-mentioned exemption/equivalency has been granted by the responsible flag Administration.

Notes:

1 Watertight subdivision means the transverse and longitudinal subdivisions of the craft required to satisfy the subdivision requirements of SOLAS Chapter II-1.

2 Major repair means a repair affecting structural integrity.
3 Testing Requirements for Craft Built in Compliance with SOLAS 1974 as Amended

3.1 Application

All gravity tanks which are subjected to vapor pressure not greater than 0.7 bar (0.7 kgf/cm², 10 psi) and other boundaries required to be watertight or weathertight are to be tested in accordance with this Subsection and proven to be tight or structurally adequate as follows:

3.1.1 Gravity Tanks for their structural adequacy and tightness,

3.1.2 Watertight Boundaries Other Than Tank Boundaries for their watertightness, and

3.1.3 Weathertight Boundaries for their weathertightness.

Testing of structures not listed in 3-7-1/3.5.7 TABLE 1 is to be specially considered.

3.3 Test Types and Definitions

3.3.1 The following two types of tests are specified in this requirement.

3.3.1(a) Structural Test.

A test to verify the structural adequacy of tank construction. This may be a hydrostatic test or, where the situation warrants, a hydropneumatic test.

3.3.1(b) Leak Test.

A test to verify the tightness of a boundary. Unless a specific test is indicated, this may be a hydrostatic/hydropneumatic test or an air test. A hose test may be considered an acceptable form of leak test for certain boundaries, as indicated by Note 3 of 3-7-1/3.5.7 TABLE 1.

3.3.2 The definition of each test type is as follows:

<table>
<thead>
<tr>
<th>Test Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hydrostatic Test: (Leak and Structural)</td>
<td>A test wherein a space is filled with a liquid to a specified head.</td>
</tr>
<tr>
<td>Hydropneumatic Test: (Leak and Structural)</td>
<td>A test combining a hydrostatic test and an air test, wherein a space is partially filled with a liquid and pressurized with air.</td>
</tr>
<tr>
<td>Hose Test: (Leak)</td>
<td>A test to verify the tightness of a joint by a jet of water with the joint visible from the opposite side.</td>
</tr>
<tr>
<td>Air Test: (Leak)</td>
<td>A test to verify tightness by means of air pressure differential and leak indicating solution. It includes tank air test and joint air tests, such as compressed air fillet weld tests and vacuum box tests.</td>
</tr>
<tr>
<td>Compressed Air Fillet Weld Test: (Leak)</td>
<td>An air test of fillet welded tee joints wherein leak indicating solution is applied on fillet welds.</td>
</tr>
<tr>
<td>Vacuum Box Test: (Leak)</td>
<td>A box over a joint with leak indicating solution applied on the welds. A vacuum is created inside the box to detect any leaks.</td>
</tr>
</tbody>
</table>
### 3.5 Test Procedures

#### 3.5.1 General

Tests are to be carried out in the presence of a Surveyor at a stage sufficiently close to the completion of work with all hatches, doors, windows, etc., installed and all penetrations including pipe connections fitted, and before any ceiling and cement work is applied over the joints. Specific test requirements are given in 3-7-1/3.5.4 and 3-7-1/3.5.7 TABLE 1. For the timing of the application of coating and the provision of safe access to joints, see 3-7-1/3.5.5, 3-7-1/3.5.6, and 3-7-1/3.5.7 TABLE 2.

#### 3.5.2 Structural Test Procedures

**3.5.2(a) Type and Time of Test.**

Where a structural test is specified in 3-7-1/3.5.7 TABLE 1, a hydrostatic test in accordance with 3-7-1/3.5.4(a) will be acceptable. Where practical limitations (strength of building berth, light density of liquid, etc.) prevent the performance of a hydrostatic test, a hydropneumatic test in accordance with 3-7-1/3.5.4(b) may be accepted instead.

A hydrostatic test or hydropneumatic test for the confirmation of structural adequacy may be carried out while the craft is afloat, provided the results of a leak test are confirmed to be satisfactory before the craft is afloat.

**3.5.2(b) Testing Schedule for New Construction or Major Structural Conversion.**

i) Tanks which are intended to hold liquids, and which form part of the watertight subdivision of the craft*, shall be tested for tightness and structural strength as indicated in 3-7-1/3.5.7 TABLE 1.

ii) The tank boundaries are to be tested from at least one side. The tanks for structural test are to be selected so that all representative structural members are tested for the expected tension and compression.

iii) The watertight boundaries of spaces other than tanks for structural testing may be exempted, provided that the watertightness of boundaries of exempted spaces is verified by leak tests and inspections. Structural testing may not be exempted and the requirements for structural testing of tanks in 3-7-1/3.5.2(b)i) to 3-7-1/3.5.2(b)iii) shall apply, for ballast holds, chain lockers and a representative cargo hold if intended for import ballasting.

iv) Tanks which do not form part of the watertight subdivision of the craft*, may be exempted from structural testing provided that the watertightness of boundaries of exempted spaces is verified by leak tests and inspections.

Note:

*Watertight subdivision means the main transverse and longitudinal subdivisions of the craft required to satisfy the subdivision requirements of SOLAS Chapter II-1.

#### 3.5.3 Leak Test Procedures

For the leak tests specified in 3-7-1/3.5.7 TABLE 1, tank air tests, compressed air fillet weld tests, vacuum box tests in accordance with 3-7-1/3.5.4(d) through 3-7-1/3.5.4(f), or their combination, will be acceptable. Hydrostatic or hydropneumatic tests may also be accepted as leak tests.
provided that 3-7-1/3.5.5, 3-7-1/3.5.6, and 3-7-1/3.5.7 are complied with. Hose tests will also be acceptable for such locations as specified in 3-7-1/3.5.7 TABLE 1, note 3, in accordance with 3-7-1/3.5.4(c).

The application of the leak test for each type of welded joint is specified in 3-7-1/3.5.7 TABLE 2.

Air tests of joints may be carried out in the block stage provided that all work on the block that may affect the tightness of a joint is completed before the test. See also 3-7-1/3.5.5(a) for the application of final coatings and 3-7-1/3.5.6 for the safe access to joints and the summary in 3-7-1/3.5.7 TABLE 2.

3.5.4 Test Methods

3.5.4(a) Hydrostatic Test.

Unless another liquid is approved, hydrostatic tests are to consist of filling the space with fresh water or sea water, whichever is appropriate for testing, to the level specified in 3-7-1/3.5.7 TABLE 1. See also 3-7-1/3.5.7.

In cases where a tank is designed for cargo densities greater than sea water and testing is with fresh water or sea water, the testing pressure height is to simulate the actual loading for those greater cargo densities as far as practicable.

All external surfaces of the tested space are to be examined for structural distortion, bulging and buckling, other related damage and leaks.

3.5.4(b) Hydropneumatic Test.

Hydropneumatic tests, where approved, are to be such that the test condition, in conjunction with the approved liquid level and supplemental air pressure, will simulate the actual loading as far as practicable. The requirements and recommendations for tank air tests in 3-7-1/3.5.4(d) will also apply to hydropneumatic tests. See also 3-7-1/3.5.7.

All external surfaces of the tested space are to be examined for structural distortion, bulging and buckling, other related damage and leaks.

3.5.4(c) Hose Test.

Hose tests are to be carried out with the pressure in the hose nozzle maintained at least at 2 bar (2 kgf/cm², 30 psi) during the test. The nozzle is to have a minimum inside diameter of 12 mm (0.5 in.) and be at a perpendicular distance from the joint not exceeding 1.5 m (5 ft). The water jet is to impinge directly upon the weld.

Where a hose test is not practical because of possible damage to machinery, electrical equipment insulation or outfitting items, it may be replaced by a careful visual examination of welded connections, supported where necessary by means such as a dye penetrant test or ultrasonic leak test or the equivalent.

3.5.4(d) Tank air Test.

All boundary welds, erection joints and penetrations, including pipe connections, are to be examined in accordance with approved procedure and under a stabilized pressure differential above atmospheric pressure not less than 0.15 bar (0.15 kgf/cm², 2.2 psi), with a leak indicating solution such as soapy water/detergent or a proprietary brand applied.

A U-tube with a height sufficient to hold a head of water corresponding to the required test pressure is to be arranged. The cross sectional area of the U-tube is not to be less than that of the pipe supplying air to the tank. Arrangements involving the use of two calibrated pressure gauges to verify the required test pressure may be accepted taking into account the provisions in F5.1 and

Other effective methods of air testing, including compressed air fillet weld testing or vacuum testing, may be considered in accordance with 3-7-1/3.5.4(i).

A double inspection is to be made of tested welds. The first is to be immediately upon applying the leak indication solution; the second is to be after approximately four or five minutes, without further application of leak indication solution, in order to detect those smaller leaks which may take time to appear.

3.5.4(e) Compressed Air Fillet Weld Test.
In this air test, compressed air is injected from one end of a fillet welded joint and the pressure verified at the other end of the joint by a pressure gauge. Pressure gauges are to be arranged so that an air pressure of at least 0.15 bar (0.15 kgf/cm$^2$, 2.2 psi) can be verified at each end of all passages within the portion being tested.

For limited portions of the partial penetration or fillet welded joints forming tank boundaries, such as corners and section of the weld adjacent to the testing apparatus, the attending Surveyor may accept the use of Magnetic Particle Inspection or Dye Penetration examination as an alternative to fillet air testing.

Where a leaking test of partial penetration welding is required and the root face is sufficiently large such as 6-8 mm (0.24-0.32 inch), the compressed air test is to be applied in the same manner as for a fillet weld.

3.5.4(f) Vacuum Box Test.
A box (vacuum testing box) with air connections, gauges and an inspection window is placed over the joint with a leak indicating solution applied to the weld cap vicinity. The air within the box is removed by an ejector to create a vacuum of 0.20 bar (0.20 kgf/cm$^2$, 2.9 psi) – 0.26 bar (0.27 kgf/cm$^2$, 3.8 psi) inside the box.

3.5.4(g) Ultrasonic Test.
An ultrasonic echo transmitter is to be arranged inside of a compartment and a receiver is to be arranged on the outside. The watertight/weather tight boundaries of the compartment are scanned with the receiver in order to detect an ultrasonic leak indication. A location where sound is detectable by the receiver indicates a leakage in the sealing of the compartment.

3.5.4(h) Penetration Test.
A test of butt welds or other weld joints uses the application of a low surface tension liquid at one side of a compartment boundary or structural arrangement. If no liquid is detected on the opposite sides of the boundaries after the expiration of a defined period of time, this indicates tightness of the boundaries. In certain cases, a developer solution may be painted or sprayed on the other side of the weld to aid leak detection.

3.5.4(i) Other Test.
Other methods of testing, except as provided in 3-7-1/5, may be considered upon submission of full particulars prior to the commencement of testing.

3.5.5 Application of Coating
3.5.5(a) Final Coating.
For butt joints welded by an automatic process, the final coating may be applied any time before the completion of a leak test of spaces bounded by the joints, provided that the welds have been carefully inspected visually to the satisfaction of the Surveyor.
Surveyors reserve the right to require a leak test prior to the application of final coating over automatic erection butt welds.

For all other joints, the final coating is to be applied after the completion of the leak test of the joint. See also 3-7-1/3.5.7 TABLE 2.

3.5.5(b) Temporary Coating.
Any temporary coating which may conceal defects or leaks is to be applied at the time as specified for the final coating [see 3-7-1/3.5.5(a)]. This requirement does not apply to shop primer.

3.5.6 Safe Access to Joints
For leak tests, safe access to all joints under examination is to be provided. See also 3-7-1/3.5.7 TABLE 2.

3.5.7 Hydrostatic or Hydropneumatic Tightness Test
In cases where the hydrostatic or hydropneumatic tests are applied instead of a specific leak test, examined boundaries must be dew-free, otherwise small leaks are not visible.

</tr>
</tbody>
</table>

Notes:

1 (2018) Refer to 3-7-1/3.5.2(b).
2 Top of tank is the deck forming the top of the tank, excluding any hatchways.
3 (2018) Hose Test may also be considered as a medium of the test. See 3-7-1/3.3.2.
4 Including tanks arranged in accordance with the provisions of SOLAS regulation II-1/9.4
5 (2016) Including duct keels and dry compartments arranged in accordance with the provisions of SOLAS regulation II-1/11.2 and II-1/9.4 respectively, and/or oil fuel tank protection and pump room bottom protection arranged in accordance with the provisions of MARPOL Annex I, Chapter 3, Part A regulation 12A and Chapter 4, Part A, regulation 22, respectively.
6 Where water tightness of a watertight door has not confirmed by prototype test, testing by filling watertight spaces with water is to be carried out. See SOLAS regulation II-1/16.2 and MSC/Circ.1176.
7 (2018) As an alternative to the hose testing, other testing methods listed in 3-7-1/3.5.4(g) through 3-7-1/3.5.4(i) may be applicable subject to adequacy of such testing methods being verified. See SOLAS regulation II-1/11.1. For watertight bulkheads (item 11.1) alternatives to the hose testing may only be used where a hose test is not practicable.
8 (2018) A “Leak and structural test”, see 3-7-1/3.5.2(b), is to be carried out for a representative cargo hold if intended for in-port ballasting. The filling level requirement for testing cargo holds intended for in-port ballasting is to be the maximum loading that will occur in-port as indicated in the loading manual.
9 (2018) Where L.O. sump tanks and other similar spaces under main engines intended to hold liquid form part of the watertight subdivision of the craft, they are to be tested as per the requirements of Item 5, Deep tanks other than those listed elsewhere in this table.
### TABLE 2

Notes:
1. Coating refers to internal (tank/hold coating), where applied, and external (shell/deck) painting. It does not refer to shop primer.
2. Temporary means of access for verification of the leak testing.
3. The condition applies provided that the welds have been carefully inspected visually to the satisfaction of the Surveyor.
4. (2016) Flux Core Arc Welding (FCAW) semiautomatic butt welds need not be tested provided that careful visual inspections show continuous uniform weld profile shape, free from repairs, and the results of the Rule and Surveyor required NDE testing show no significant defects.

## 5 Testing Requirements for Craft Not Built in Compliance with SOLAS 1974 as Amended

### 5.1
Testing procedures are to be carried out in accordance with the requirements of 3-7-1/3 in association with the following alternative procedures for 3-7-1/3.5.2(b) “Testing Schedule for New Construction or Major Structural Conversion” and alternative test requirements for 3-7-1/3.5.7 TABLE 1.

### 5.3
The tank boundaries are to be tested from at least one side. The tanks for structural test are to be selected so that all representative structural members are tested for the expected tension and compression.

### 5.5
Structural tests are to be carried out for at least one tank of a group of tanks having structural similarity (i.e., same design conditions, alike structural configurations with only minor localized differences determined to be acceptable by the attending Surveyor) on each craft provided all other tanks are tested for leaks by an air test. The acceptance of leak testing using an air test instead of a structural test does not apply to cargo space boundaries adjacent to other compartments in tankers and combination carriers or to the boundaries of tanks for segregated cargoes or pollutant cargoes in other types of ships.
5.7

Additional tanks may require structural testing if found necessary after the structural testing of the first tank.

5.9

Where the structural adequacy of the tanks of a craft were verified by the structural testing required in 3-7-1/3.5.7 TABLE 1, subsequent craft in the series (i.e. sister ships built from the same plans at the same shipyard) may be exempted from structural testing of tanks, provided that:

i) Water-tightness of boundaries of all tanks is verified by leak tests and thorough inspections are carried out

ii) Structural testing is carried out for at least one tank of each type among all tanks of each sister craft

iii) Additional tanks may require structural testing if found necessary after the structural testing of the first tank or if deemed necessary by the attending Surveyor

For cargo space boundaries adjacent to other compartments in tankers and combination carriers or boundaries of tanks for segregated cargoes or pollutant cargoes in other types of ships, the provisions of 3-7-1/5.3 shall apply in lieu of 3-7-1/5.5.

5.11

Sister craft built (i.e., keel laid) two years or more after the delivery of the last craft of the series, may be tested in accordance with 3-7-1/5.5 at the discretion of the Surveyor, provided that:

i) General workmanship has been maintained (i.e., there has been no discontinuity of shipbuilding or significant changes in the construction methodology or technology at the yard and shipyard personnel are appropriately qualified and demonstrate an adequate level of workmanship as determined by the Surveyor).

ii) An NDT plan is implemented and evaluated by the Surveyor for the tanks not subject to structural tests. Shipbuilding quality standards for the hull structure during new construction are to be reviewed and agreed during the kick-off meeting. Structural fabrication is to be carried out in accordance with IACS Recommendation 47, “Shipbuilding and Repair Quality Standard”, or a recognized fabrication standard to the satisfaction of the attending Surveyor prior to the commencement of fabrication/construction. The work is to be carried out in accordance with the Rules and under survey of the Surveyor.
Testing, Trials and Surveys During Construction – Hull

Trials

1 Anchor Windlass Trials

Each windlass is to be tested under working conditions after installation onboard to demonstrate satisfactory operation. Each unit is to be independently tested for braking, clutch functioning, lowering and hoisting of chain cable and anchor, proper riding of the chain over the chain lifter, proper transit of the chain through the hawse pipe and the chain pipe, and effecting proper stowage of the chain and the anchor. It is to be confirmed that anchors properly seat in the stored position and that chain stoppers function as designed if fitted. Also, it is to be demonstrated that the windlass is capable of lifting each anchor with 82.5 meters (45 fathoms) length of chain submerged and hanging free. The braking capacity is to be tested by intermittently paying out and holding the chain cable by means of the application of the brake. Where the available water depth is insufficient, the proposed test method will be specially considered.

3 Bilge System Trials

All elements of the bilge system are to be tested to demonstrate satisfactory pumping operation, including emergency suctions and all controls. Upon completion of the trials, the bilge strainers are to be opened, cleaned and closed up in good order.

5 Steering Trials

Refer to 4-3-3/15 for the technical details of the steering trials.
CHAPTER 7 Testing, Trials and Surveys During Construction – Hull

SECTION 3 Surveys

1 Construction Welding and Fabrication
For surveys of hull construction welding and fabrication, refer to Chapter 4 of the ABS Rules for Materials and Welding (Part 2) and Section 2-4-5 of the ABS Rules for Materials and Welding (Part 2) and to the ABS Guide for Nondestructive Inspection of Hull Welds.

3 Hull Castings and Forgings
For surveys in connection with the manufacture and testing of hull castings and forgings, refer to Chapter 1 of the ABS Rules for Materials and Welding (Part 2).

5 Piping
For surveys in connection with the manufacture and testing of piping, refer to Part 4, Chapter 4 of these Rules.
